# ICS94203

## General Description

The **ICS94203** is a single chip clock solution for desktop designs using the 810/810E and Solano style chipset. It provides all necessary clock signals for such a system.

The **ICS94203** belongs to ICS new generation of programmable system clock generators. It employs serial programming I<sup>2</sup>C interface as a vehicle for changing output functions, changing output frequency, configuring output strength, configuring output to output skew, changing spread spectrum amount, changing group divider ratio and dis/enabling individual clocks. This device also has ICS propriety 'Watchdog Timer' technology which will reset the frequency to a safe setting if the system become unstable from over clocking.

Spread spectrum typically reduces system EMI by 7dB to 8dB. This simplifies EMI qualification without resorting to board design iterations or costly shielding.

### Notes:

- The ICS clock generator is a slave/receiver, I<sup>2</sup>C component. It can read back the data stored in the latches for verification. Readback will support standard SMBUS controller protocol. **The number of bytes to readback is defined by writing to byte 6.**
- When writing to byte 14 - 15, byte 16 - 17 and byte 18 - 20, they must be written as a set.** If for example, only byte 14 is written but not 15, neither byte 14 or 15 will load into the receiver.
- The data transfer rate supported by this clock generator is 100K bits/sec or less (standard mode)
- The input is operating at 3.3V logic levels.
- The data byte format is 8 bit bytes.
- To simplify the clock generator I<sup>2</sup>C interface, the protocol is set to use only Block-Writes from the controller. The bytes must be accessed in sequential order from lowest to highest byte with the ability to stop after any complete byte has been transferred. The Command code and Byte count shown above must be sent, but the data is ignored for those two bytes. The data is loaded until a Stop sequence is issued.
- At power-on, all registers are set to a default condition, as shown.

### VCO Programming Constrains

VCO Frequency ..... 150MHz to 500MHz

VCO Divider Range ..... 8 to 519

REF Divider Range ..... 2 to 129

Phase Detector Stability ..... 0.3536 to 1.4142

### Useful Formula

VCO Frequency =  $14.31818 \times \text{VCO/REF divider value}$

Phase Detector Stabiliy =  $14.038 \times (\text{VCO divider value})^{-0.5}$

### To program the VCO frequency for over-clocking.

- Before trying to program our clock manually, consider using ICS provided software utilities for easy programming.
- Select the frequency you want to over-clock from with the desire gear ratio (i.e. CPU:SDRAM:3V66:PCI ratio) by writing to byte 0, or using initial hardware power up frequency.
- Write 0001, 0111 (17H) to byte 6 for readback of 23 bytes (byte 0-22).
- Read back byte 16-24 and copy values in these registers.
- Re-initialize the write sequence.
- Write a '1' to byte 8 bit 7 indicating you want to use byte 14 and 15 to control the VCO frequency.
- Write to byte 14 & 15 with the desired VCO & REF divider values.
- Write to byte 16 to 22 with the values you copy from step 3. This maintains the output divider mux controls the same gear ratio.
- The above procedure is only needed when changing the VCO for the 1st pass. If VCO frequency needed to be changed again, user only needs to write to byte 14 and 15 unless the system is to reboot.

**Note:**

1. User needs to ensure step 3 & 7 is carried out. Systems with wrong spread percentage and/or group to group divider ratio programmed into bytes 16-20 could be unstable. Step 3 & 7 assure the correct spread and gear ratio.
2. If VCO, REF divider values or phase detector stability are out of range, the device may fail to function correctly.
3. Follow min and max VCO frequency range provided. Internal PLL could be unstable if VCO frequency is too fast or too slow. Use  $14.31818\text{MHz} \times \text{VCO/REF divider values}$  to calculate the VCO frequency (MHz).
4. Users can also utilize software utility provided to program VCO frequency from ICS Application Engineering.
5. Spread percent needs to be calculated based on VCO frequency, spread modulation frequency and spread amount desired. See Application note for software support.

### Notes:

1. PWD = Power on Default
2. The power on default for byte 16-20 depends on the hardware (latch inputs FS[0:4]) or I<sup>2</sup>C (Byte 0 bit [1:7]) setting. Be sure to read back and re-write the values of these 5 registers when VCO frequency change is desired for the first pass.

## Shared Pin Operation - Input/Output Pins

The I/O pins designated by (input/output) on the ICS94203 serve as dual signal functions to the device. During initial power-up, they act as input pins. The logic level (voltage) that is present on these pins at this time is read and stored into a 5-bit internal data latch. At the end of Power-On reset, (see AC characteristics for timing values), the device changes the mode of operations for these pins to an output function. In this mode the pins produce the specified buffered clocks to external loads.

To program (load) the internal configuration register for these pins, a resistor is connected to either the VDD (logic 1) power supply or the GND (logic 0) voltage potential. A 10 Kilohm (10K) resistor is used to provide both the solid CMOS programming voltage needed during the power-up programming period and to provide an insignificant load on the output clock during the subsequent operating period.

Figure 1 shows a means of implementing this function when a switch or 2 pin header is used. With no jumper is installed the pin will be pulled high. With the jumper in place the pin will be pulled low. If programmability is not necessary, than only a single resistor is necessary. The programming resistors should be located close to the series termination resistor to minimize the current loop area. It is more important to locate the series termination resistor close to the driver than the programming resistor.
