# PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

## 1 FEATURES

### 1.1 Video decoder

- Six analog inputs, internal analog source selectors, e.g.  $6 \times$  CVBS or  $(2 \times$  Y/C and  $2 \times$  CVBS) or  $(1 \times$  Y/C and  $4 \times$  CVBS)
- Two analog preprocessing channels in differential CMOS style inclusive built-in analog anti-alias filters
- Fully programmable static gain or Automatic Gain Control (AGC) for the selected CVBS or Y/C channel
- Automatic Clamp Control (ACC) for CVBS, Y and C
- Switchable white peak control
- Two 9-bit video CMOS Analog-to-Digital Converters (ADCs), digitized CVBS or Y/C signals are available on the expansion port
- On-chip line-locked clock generation according "ITU 601"
- Digital PLL for synchronization and clock generation from all standards and non-standard video sources e.g. consumer grade VTR
- Requires only one crystal (32.11 or 24.576 MHz) for all standards
- Horizontal and vertical sync detection
- Automatic detection of 50 and 60 Hz field frequency, and automatic switching between PAL and NTSC standards
- Luminance and chrominance signal processing for PAL BGDHIN, combination PAL N, PAL M, NTSC M, NTSC-Japan, NTSC 4.43 and SECAM
- Adaptive 2/4-line comb filter for two dimensional chrominance/luminance separation
  - Increased luminance and chrominance bandwidth for all PAL and NTSC standards
  - Reduced cross colour and cross luminance artefacts
- PAL delay line for correcting PAL phase errors
- Independent Brightness Contrast Saturation (BCS) adjustment for decoder part
- User programmable sharpness control
- Independent gain and offset adjustment for raw data path.

### 1.2 Video scaler

- Horizontal and vertical down-scaling and up-scaling to randomly sized windows
- Horizontal and vertical scaling range: variable zoom to  $\frac{1}{64}$  (icon); it should be noted that the H and V zoom are restricted by the transfer data rates
- Anti-alias and accumulating filter for horizontal scaling
- Vertical scaling with linear phase interpolation and accumulating filter for anti-aliasing (6-bit phase accuracy)
- Horizontal phase correct up and down scaling for improved signal quality of scaled data, especially for compression and video phone applications, with 6-bit phase accuracy (1.2 ns step width)
- Two independent programming sets for scaler part, to define two 'ranges' per field or sequences over frames
- Fieldwise switching between decoder part and expansion port (X-port) input
- Brightness, contrast and saturation controls for scaled outputs.

### 1.3 Vertical Blanking Interval (VBI) data decoder and slicer

- Versatile VBI-data decoder, slicer, clock regeneration and byte synchronization e.g. for World Standard Teletext (WST), North-American Broadcast Text System (NABTS), close caption, Wide Screen Signalling (WSS) etc.

### 1.4 Audio clock generation

- Generation of a field locked audio master clock to support a constant number of audio clocks per video field
- Generation of an audio serial and left/right (channel) clock signal.

# PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

## 1.5 Digital I/O interfaces

- Real-time signal port (R port), inclusive continuous line-locked reference clock and real-time status information supporting RTC level 3.1 (refer to external document “*RTC Functional Specification*” for details)
- Bi-directional expansion port (X-port) with half duplex functionality (D1), 8-bit YUV
  - Output from decoder part, real-time and unscaled
  - Input to scaler part, e.g. video from MPEG decoder (extension to 16-bit possible)
- Video image port (I-port) configurable for 8-bit data (extension to 16-bit possible) in master mode (own clock), or slave mode (external clock), with auxiliary timing and hand shake signals
- Discontinuous data streams supported
- 32-word × 4-byte FIFO register for video output data
- 28-word × 4-byte FIFO register for decoded VBI output data
- Scaled 4 : 2 : 2, 4 : 1 : 1, 4 : 2 : 0, 4 : 1 : 0 YUV output
- Scaled 8-bit luminance only and raw CVBS data output
- Sliced, decoded VBI-data output.

## 1.6 Miscellaneous

- Power-on control
- 5 V tolerant digital inputs and I/O ports
- Software controlled power saving standby modes supported
- Programming via serial I<sup>2</sup>C-bus, full read-back ability by an external controller, bit rate up to 400 kbits/s
- Boundary scan test circuit complies with the “*IEEE Std. 1149.b1 - 1994*”.

## 2 APPLICATIONS

- Desktop video
- Multimedia
- Digital television
- Image processing
- Video phone applications.

## 3 GENERAL DESCRIPTION

The SAA7114H is a video capture device for applications at the image port of VGA controllers.

The SAA7114H is a combination of a two-channel analog preprocessing circuit including source selection, anti-aliasing filter and ADC, an automatic clamp and gain control, a Clock Generation Circuit (CGC), a digital multi-standard decoder containing two-dimensional chrominance/luminance separation by an adaptive comb filter and a high performance scaler, including variable horizontal and vertical up and down scaling and a brightness, contrast and saturation control circuit.

It is a highly integrated circuit for desktop video applications. The decoder is based on the principle of line-locked clock decoding and is able to decode the colour of PAL, SECAM and NTSC signals into ITU 601 compatible colour component values. The SAA7114H accepts as analog inputs CVBS or S-video (Y/C) from TV or VCR sources, including weak and distorted signals. An expansion port (X-port) for digital video (bi-directional half duplex, D1 compatible) is also supported to connect to MPEG or video phone codec. At the so called image port (I-port) the SAA7114H supports 8 or 16-bit wide output data with auxiliary reference data for interfacing to VGA controllers.

The target application for SAA7114H is to capture and scale video images, to be provided as digital video stream through the image port of a VGA controller, for display via VGA's frame buffer, or for capture to system memory.

In parallel SAA7114H incorporates also provisions for capturing the serially coded data in the vertical blanking interval (VBI-data). Two principal functions are available:

1. To capture raw video samples, after interpolation to the required output data rate, via the scaler
2. A versatile data slicer (data recovery) unit.

SAA7114H incorporates also a field locked audio clock generation. This function ensures that there is always the same number of audio samples associated with a field, or a set of fields. This prevents the loss of synchronization between video and audio, during capture or playback.

The circuit is I<sup>2</sup>C-bus controlled (full write/read capability for all programming registers, bit rate up to 400 kbits/s).

**7 PINNING**

SYMBOL	PIN	TYPE	DESCRIPTION
V <sub>DDD(EP1)</sub>	1	P	external digital pad supply voltage 1 (+3.3 V)
TDO	2	O	test data output for boundary scan test; note 1
TDI	3	I	test data input for boundary scan test; note 1
XTOUT	4	O	crystal oscillator output signal; auxiliary signal
V <sub>SS(XTAL)</sub>	5	P	ground for crystal oscillator
XTALO	6	O	24.576 MHz (32.11 MHz) crystal oscillator output; not connected if TTL clock input of XTALI is used
XTALI	7	I	input terminal for 24.576 MHz (32.11 MHz) crystal oscillator or connection of external oscillator with TTL compatible square wave clock signal
V <sub>DD(XTAL)</sub>	8	P	supply voltage for crystal oscillator
V <sub>SSA2</sub>	9	P	ground for analog inputs AI2n
AI24	10	I	analog input 24
V <sub>DDA2</sub>	11	P	analog supply voltage for analog inputs AI2n (+3.3 V)
AI23	12	I	analog input 23
AI2D	13	I	differential input for ADC channel 2 (pins AI24, AI23, AI22 and AI21)
AI22	14	I	analog input 22
V <sub>SSA1</sub>	15	P	ground for analog inputs AI1n
AI21	16	I	analog input 21
V <sub>DDA1</sub>	17	P	analog supply voltage for analog inputs AI1n (+3.3 V)
AI12	18	I	analog input 12
AI1D	19	I	differential input for ADC channel 1 (pins AI12 and AI11)
AI11	20	I	analog input 11
AGND	21	P	analog ground connection
AOUT	22	O	do not connect; analog test output
V <sub>DDA0</sub>	23	P	analog supply voltage (+3.3 V) for internal Clock Generation Circuit (CGC)
V <sub>SSA0</sub>	24	P	ground for internal clock generation circuit
V <sub>DDD(EP2)</sub>	25	P	external digital pad supply voltage 2 (+3.3 V)
V <sub>SSD(EP1)</sub>	26	P	external digital pad supply ground 1
CE	27	I	chip enable or reset input (with internal pull-up)
LLC	28	O	line-locked system clock output (27 MHz nominal)
LLC2	29	O	line-locked 1/2 clock output (13.5 MHz nominal)
RES	30	O	reset output (active LOW)
SCL	31	I(O)	serial clock input (I <sup>2</sup> C-bus) with inactive output path
SDA	32	I/O	serial data input/output (I <sup>2</sup> C-bus)
V <sub>DDD(IC01)</sub>	33	P	internal digital core supply voltage 1 (+3.3 V)
RTS0	34	O	real-time status or sync information, controlled by subaddresses 11H and 12H;
RTS1	35	O	see Section 15.2.18, 15.2.19 and 15.2.20

**PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler**

**SAA7114H**

SYMBOL	PIN	TYPE	DESCRIPTION
RTCO	36	(I/O)	real-time control output; contains information about actual system clock frequency, field rate, odd/even sequence, decoder status, subcarrier frequency and phase and PAL sequence (see external document " <i>RTC Functional Description</i> ", available on request); the RTCO pin is enabled via I <sup>2</sup> C-bus bit RTCE; see notes 2, 3 and Table 34
AMCLK	37	O	audio master clock output, up to 50% of crystal clock
V <sub>SSD(ICO1)</sub>	38	P	internal digital core supply ground 1
ASCLK	39	O	audio serial clock output
ALRCLK	40	(I/O)	audio left/right clock output; can be strapped to supply via a 3.3 kΩ resistor to indicate that the default 24.576 MHz crystal (ALRCLK = 0; internal pull-down) has been replaced by a 32.110 MHz crystal (ALRCLK = 1); see notes 2 and 4
AMXCLK	41	I	audio master external clock input
ITRDY	42	I	target ready input, image port (with internal pull-up)
V <sub>DDD(ICO2)</sub>	43	P	internal digital core supply voltage 2 (+3.3 V)
TEST0	44	O	do not connect; reserved for future extensions and for testing: scan output
ICLK	45	I/O	clock output signal for image port, or optional asynchronous back-end clock input
IDQ	46	O	output data qualifier for image port (optional: gated clock output)
ITRI	47	I(O)	image port output control signal, effects all input port pins inclusive ICLK, enable and active polarity is under software control (bits IPE in subaddress 87H); output path used for testing: scan output
IGP0	48	O	general purpose output signal 0; image port (controlled by subaddresses 84H and 85H)
IGP1	49	O	general purpose output signal 1; image port (controlled by subaddresses 84H and 85H)
V <sub>SSD(EP2)</sub>	50	P	external digital pad supply ground 2
V <sub>DDD(EP3)</sub>	51	P	external digital pad supply voltage 3 (+3.3 V)
IGPV	52	O	multi purpose vertical reference output signal; image port (controlled by subaddresses 84H and 85H)
IGPH	53	O	multi purpose horizontal reference output signal; image port (controlled by subaddresses 84H and 85H)
IPD7 to IPD4	54 to 57	O	image port data outputs
V <sub>DDD(ICO3)</sub>	58	P	internal digital core supply voltage 3 (+3.3 V)
IPD3 to IPD0	59 to 62	O	image port data output
V <sub>SSD(ICO2)</sub>	63	P	internal digital core supply ground 2
HPD7 to HPD4	64 to 67	I/O	host port data I/O, carries UV chrominance information in 16-bit video I/O modes
V <sub>DDD(ICO4)</sub>	68	P	internal digital core supply voltage 4 (+3.3 V)
HPD3 to HPD0	69 to 72	I/O	host port data I/O, carries UV chrominance information in 16-bit video I/O modes
TEST1	73	I	do not connect; reserved for future extensions and for testing: scan input
TEST2	74	I	do not connect; reserved for future extensions and for testing: scan input
V <sub>DDD(EP4)</sub>	75	P	external digital pad supply voltage 4 (+3.3 V)
V <sub>SSD(EP3)</sub>	76	P	external digital pad supply ground 3
TEST3	77	I	do not connect; reserved for future extensions and for testing: scan input

comb filter, VBI-data slicer and high performance scaler**

**SAA7114H**

SYMBOL	PIN	TYPE	DESCRIPTION
TEST4	78	O	do not connect; reserved for future extensions and for testing: scan output
TEST5	79	I	do not connect; reserved for future extensions and for testing: scan input
XTRI	80	I	X-port output control signal, affects all X-port pins (XPD7 to XPD0, XRH, XRV, XDQ and XCLK), enable and active polarity is under software control (bits XPE in subaddress 83H)
XPD7	81	I/O	expansion port data
XPD6	82	I/O	expansion port data
V <sub>DD(ICO5)</sub>	83	P	internal digital core supply voltage 5 (+3.3 V)
XPD5 to XPD2	84 to 87	I/O	expansion port data
V <sub>SS(ICO3)</sub>	88	P	internal digital core supply ground 3
XPD1	89	I/O	expansion port data
XPD0	90	I/O	expansion port data
XRV	91	I/O	vertical reference I/O expansion port
XRH	92	I/O	horizontal reference I/O expansion port
V <sub>DD(ICO6)</sub>	93	P	internal digital core supply voltage 6 (+3.3 V)
XCLK	94	I/O	clock I/O expansion port
XDQ	95	I/O	data qualifier I/O expansion port
XRDY	96	O	task flag or ready signal from scaler, controlled by XRQT
$\overline{\text{TRST}}$	97	I	test reset input (active LOW), for boundary scan test (with internal pull-up); notes 5 and 6
TCK	98	I	test clock for boundary scan test; note 1
TMS	99	I	test mode select input for boundary scan test or scan test; note 1
V <sub>SS(EP4)</sub>	100	P	external digital pad supply ground 4

### Notes

1. In accordance with the "IEEE1149.1" standard the pads TDI, TMS, TCK and  $\overline{\text{TRST}}$  are input pads with an internal pull-up transistor and TDO is a 3-state output pad.
2. Pin strapping is done by connecting the pin to supply via a 3.3 k $\Omega$  resistor. During the power-up reset sequence the corresponding pins are switched to input mode to read the strapping level. For the default setting no strapping resistor is necessary (internal pull-down).
3. Pin RTCO: operates as I<sup>2</sup>C-bus slave address pin; RTCO = 0 slave address 42H/43H (default); RTCO = 1 slave address 40H/41H.
4. Pin ALRCLK: 0 = 24.576 MHz crystal (default); 1 = 32.110 MHz crystal.
5. For board design without boundary scan implementation connect the  $\overline{\text{TRST}}$  pin to ground.
6. This pin provides easy initialization of the Boundary Scan Test (BST) circuit.  $\overline{\text{TRST}}$  can be used to force the Test Access Port (TAP) controller to the TEST\_LOGIC\_RESET state (normal operation) at once.

**SAA7114H**

**8 FUNCTIONAL DESCRIPTION**

**8.1 Decoder**

**8.1.1 ANALOG INPUT PROCESSING**

The SAA7114H offers six analog signal inputs, two analog main channels with source switch, clamp circuit, analog amplifier, anti-alias filter and video 9-bit CMOS ADC; see Fig.6.

**8.1.2 ANALOG CONTROL CIRCUITS**

The anti-alias filters are adapted to the line-locked clock frequency via a filter control circuit. The characteristics are shown in Fig.3. During the vertical blanking period, gain and clamping control are frozen.

Fig.3 Anti-alias filter.

## SAA7114H

### 8.1.2.1 Clamping

The clamp control circuit controls the correct clamping of the analog input signals. The coupling capacitor is also used to store and filter the clamping voltage. An internal digital clamp comparator generates the information with respect to clamp-up or clamp-down. The clamping levels for the two ADC channels are fixed for luminance (60) and chrominance (128). Clamping time in normal use is set with the HCL pulse at the back porch of the video signal.

### 8.1.2.2 Gain control

The gain control circuit receives (via the I<sup>2</sup>C-bus) the static gain levels for the two analog amplifiers or controls one of these amplifiers automatically via a built-in Automatic Gain Control (AGC) as part of the Analog Input Control (AICO).

The AGC (automatic gain control for luminance) is used to amplify a CVBS or Y signal to the required signal amplitude, matched to the ADCs input voltage range. The AGC active time is the sync bottom of the video signal.

Signal (white) peak control limits the gain at signal overshoots. The flow charts (see Figs 7 and 8) show more details of the AGC. The influence of supply voltage variation within the specified range is automatically eliminated by clamp and automatic gain control.

Fig.4 Analog line with clamp (HCL) and gain range (HSY).

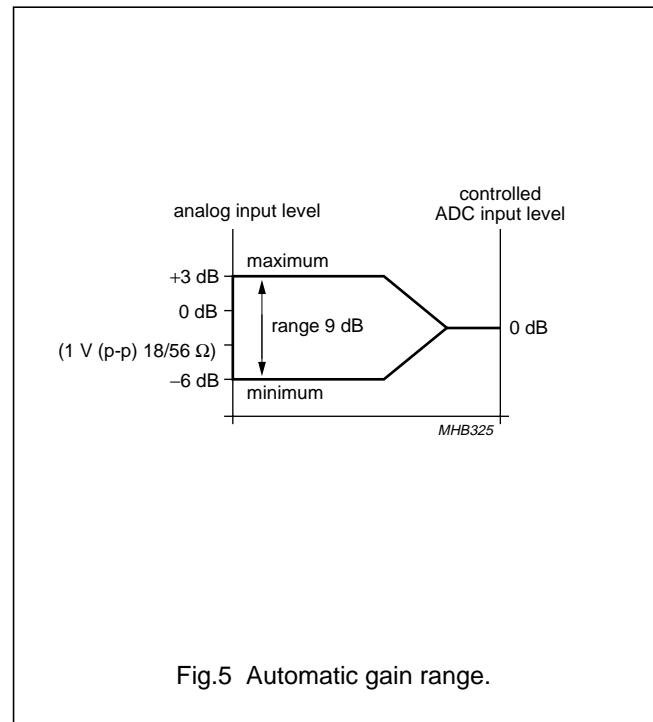

Fig.5 Automatic gain range.

### 8.1.3.1 Chrominance path

The 9-bit CVBS or chrominance input signal is fed to the input of a quadrature demodulator, where it is multiplied by two time-multiplexed subcarrier signals from the subcarrier generation block 1 (0° and 90° phase relationship to the demodulator axis). The frequency is dependent on the chosen colour standard.

The time-multiplexed output signals of the multipliers are low-pass filtered (low-pass 1). Eight characteristics are programmable via LCWB3 to LCWB0 to achieve the desired bandwidth for the colour difference signals (PAL, NTSC) or the 0° and 90° FM signals (SECAM).

The chrominance low-pass 1 characteristic also influences the grade of cross-luminance reduction during horizontal colour transients (large chrominance bandwidth means strong suppression of cross-luminance). If the Y-comb filter is disabled by YCOMB = 0 the filter influences directly the width of the chrominance notch within the luminance path (large chrominance bandwidth means wide chrominance notch resulting to lower luminance bandwidth).

The low-pass filtered signals are fed to the adaptive comb filter block. The chrominance components are separated from the luminance via a two line vertical stage (four lines for PAL standards) and a decision logic between the filtered and the non-filtered output signals. This block is bypassed for SECAM signals. The comb filter logic can be enabled independently for the succeeding luminance and chrominance processing by YCOMB (subaddress 09H, bit 6) and/or CCOMB (subaddress 0EH, bit 0). It is always bypassed during VBI or raw data lines programmable by the LCRn registers (subaddresses 41H to 57H), see Section 8.2.

The separated UV-components are further processed by a second filter stage (low-pass 2) to modify the chrominance bandwidth without influence to the luminance path. It's characteristic is controlled by CHBW (subaddress 10H, bit 3). For the complete transfer characteristic of low-passes 1 and 2 see Figs 10 and 11.

The SECAM processing (bypassed for QUAM standards) contains the following blocks:

- Baseband 'bell' filters to reconstruct the amplitude and phase equalized 0° and 90° FM signals
- Phase demodulator and differentiator (FM-demodulation)
- De-emphasis filter to compensate the pre-emphasized input signal, including frequency offset compensation (DB or DR white carrier values are subtracted from the signal, controlled by the SECAM switch signal).

The succeeding chrominance gain control block amplifies or attenuates the UV-signal according to the required ITU 601/656 levels. It is controlled by the output signal from the amplitude detection circuit within the burst processing block.

The burst processing block provides the feedback loop of the chrominance PLL and contains:

- Burst gate accumulator
- Colour identification and killer
- Comparison nominal/actual burst amplitude (PAL/NTSC standards only)
- Loop filter chrominance gain control (PAL/NTSC standards only)
- Loop filter chrominance PLL (only active for PAL/NTSC standards)
- PAL/SECAM sequence detection, H/2-switch generation.

The increment generation circuit produces the Discrete Time Oscillator (DTO) increment for both subcarrier generation blocks. It contains a division by the increment of the line-locked clock generator to create a stable phase-locked sine signal under all conditions (e.g. for non-standard signals).

The PAL delay line block eliminates crosstalk between the chrominance channels in accordance with the PAL standard requirements. For NTSC colour standards the delay line can be used as an additional vertical filter. If desired, it can be switched off by DCVF = 1. It is always disabled during VBI or raw data lines programmable by the LCRn registers (subaddresses 41H to 47H), see Section 8.2. The embedded line delay is also used for SECAM recombination (cross-over switches).

**SAA7114H****8.1.3.2 Luminance path**

The rejection of the chrominance components within the 9-bit CVBS or Y input signal is done by subtracting the re-modulated chrominance signal from the CVBS input.

The comb filtered UV-components are interpolated (upsampled) by the low-pass 3 block. It's characteristic is controlled by LUBW (subaddress 09H, bit 4) to modify the width of the chrominance 'notch' without influence to the chrominance path. The programmable frequency characteristics available in conjunction with the LCBW2 to LCBW0 settings can be seen in Figs 12 to 15. Note that these frequency curves are only valid for Y-comb disabled filter mode (YCOMB = 0). in comb filter mode the frequency response is flat. The centre frequency of the notch is automatically adapted to the chosen colour standard.

The interpolated UV-samples are multiplied by two time-multiplexed subcarrier signals from the subcarrier generation block 2. This second DTO is locked to the first subcarrier generator by an increment delay circuit matched to the processing delay, which is different for PAL and NTSC standards according to the chosen comb filter algorithm. The two modulated signals are finally added to build the re-modulated chrominance signal.

The frequency characteristic of the separated luminance signal can be further modified by the succeeding luminance filter block. It can be configured as peaking (resolution enhancement) or low-pass block by LUF13 to LUF10 (subaddress 09H, bits 3 to 0). The 16 resulting frequency characteristics can be seen in Fig.16. The LUF13 to LUF10 settings can be used as a user programmable sharpness control.

The luminance filter block also contains the adjustable Y-delay part; programmable by YDEL2 to YDEL0 (subaddress 11H, bits 2 to 0).

8.1.3.3 Brightness Contrast Saturation (BCS) control and decoder output levels

The resulting Y (CVBS) and UV-signals are fed to the BCS block, which contains the following functions:

- Chrominance saturation control by DSAT7 to DSAT0
- Luminance contrast and brightness control by DCON7 to DCON0 and DBRI7 to DBRI0
- Raw data (CVBS) gain and offset adjustment by RAWG7 to RAWG0 and RAWO7 to RAWO0
- Limiting YUV or CVBS to the values 1 (minimum) and 254 (maximum) to fulfil "ITU Recommendation 601/656".

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

- a. Sources containing 7.5 IRE black level offset (e.g. NTSC M).
- b. Sources not containing black level offset.

CVBS levels with default settings RAWG[7:0] = 64 and RAWO[7:0] = 128.  
 Equation for modification of the raw data levels via bytes RAWG and RAWO:

$$CVBS_{OUT} = \text{Int} \left[ \frac{RAWG}{64} \times (CVBS_{nom} - 128) \right] + RAWO$$

It should be noted that the resulting levels are limited to 1 to 254 in accordance with "ITU Recommendation 601/656".

**SAA7114H**

**8.1.4 SYNCHRONIZATION**

The prefiltered luminance signal is fed to the synchronization stage. Its bandwidth is further reduced to 1 MHz in a low-pass filter. The sync pulses are sliced and fed to the phase detectors where they are compared with the sub-divided clock frequency. The resulting output signal is applied to the loop filter to accumulate all phase deviations. Internal signals (e.g. HCL and HSY) are generated in accordance with analog front-end requirements. The loop filter signal drives an oscillator to generate the line frequency control signal LFCO, see Fig.19.

The detection of 'pseudo syncs' as part of the macrovision copy protection standard is also done within the synchronization circuit.

The result is reported as flag COPRO within the decoder status byte at subaddress 1FH.

**8.1.5 CLOCK GENERATION CIRCUIT**

The internal CGC generates all clock signals required for the video input processor.

The internal signal LFCO is a digital-to-analog converted signal provided by the horizontal PLL. It is the multiple of the line frequency:

$$6.75 \text{ MHz} = 429 \times f_H \text{ (50 Hz), or}$$

$$6.75 \text{ MHz} = 432 \times f_H \text{ (60 Hz).}$$

Internally the LFCO signal is multiplied by a factor of 2 and 4 in the PLL circuit (including phase detector, loop filtering, VCO and frequency divider) to obtain the output clock signals. The rectangular output clocks have a 50% duty factor.

**Table 2** Decoder clock frequencies

CLOCK	FREQUENCY (MHz)
XTALO	24.576 or 32.110
LLC	27
LLC2	13.5
LLC4 (internal)	6.75
LLC8 (virtual)	3.375

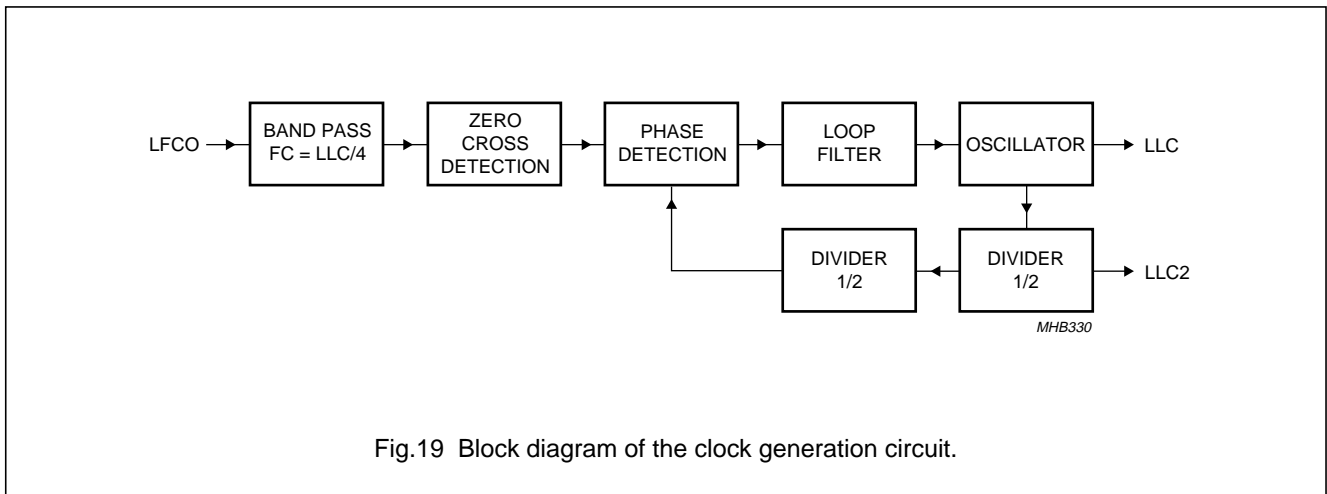

Fig.19 Block diagram of the clock generation circuit.

**8.1.6 POWER-ON RESET AND CHIP ENABLE (CE) INPUT**

A missing clock, insufficient digital or analog  $V_{DDA0}$  supply voltages (below 2.7 V) will start the reset sequence; all outputs are forced to 3-state (see Fig.20). The indicator output  $\overline{RES}$  is LOW for about 128 LLC after the internal reset and can be applied to reset other circuits of the digital TV system.

It is possible to force a reset by pulling the Chip Enable (CE) to ground. After the rising edge of CE and sufficient power supply voltage, the outputs LLC, LLC2 and SDA return from 3-state to active, while the other signals have to be activated via programming.

## 8.2 Decoder output formatter

The output interface block of the decoder part contains the ITU 656 formatter for the expansion port data output XPD7 to XPD0 (for a detailed description see Section 9.4.1) and the control circuit for the signals needed for the internal paths to the scaler and data slicer part. It also controls the selection of the reference signals for the RT port (RTCO, RTS0 and RTS1) and the expansion port (XRH, XRV and XDQ).

The generation of the decoder data type control signals SET\_RAW and SET\_VBI is also done within this block. These signals are decoded from the requested data type for the scaler input and/or the data slicer, selectable by the control registers LCR2 to LCR24 (see also Chapter 15 "I<sup>2</sup>C-bus description", subaddresses 41H to 57H).

For each LCR value from 2 to 23 the data type can be programmed individually. LCR2 to LCR23 refer to line numbers. The selection in LCR24 values is valid for the rest of the corresponding field. The upper nibble contains the value for field 1 (odd), the lower nibble for field 2 (even). The relationship between LCR values and line numbers can be adjusted via VOFF8 to VOFF0, located in subaddresses 5BH (bit 4) and 5AH (bits 7 to 0) and FOFF subaddress 5BH (bit D7). The recommended values are VOFF[8:0] = 03H for 50 Hz sources (with FOFF = 0) and VOFF[8:0] = 06H for 60 Hz sources (with FOFF = 1), to accommodate line number conventions as used for PAL, SECAM and NTSC standards; see Tables 4 to 7.

## PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

### 8.3 Scaler

The High Performance video Scaler (HPS) is based on the system as implemented in SAA7140, but enhanced in some aspects. Vertical upsampling is supported and the processing pipeline buffer capacity is enhanced, to allow more flexible video stream timing at the image port, discontinuous transfers, and handshake. The internal data flow from block to block is discontinuous dynamically, due to the scaling process itself.

The flow is controlled by internal data valid and data request flags (internal handshake signalling) between the sub-blocks. Therefore the entire scaler acts as a pipeline buffer. Depending on the actually programmed scaling parameters the effective buffer can exceed to an entire line. The access/bandwidth requirements to the VGA frame buffer are reduced significantly.

The high performance video scaler in SAA7114H has the following major blocks.

- Acquisition control (horizontal and vertical timer) and task handling (the region/field/frame based processing)
- Prescaler, for horizontal down-scaling by an integer factor, combined with appropriate band limiting filters, especially anti-aliasing for CIF format
- Brightness, saturation, contrast control for scaled output data
- Line buffer, with asynchronous read and write, to support vertical up-scaling (e.g. for videophone application, converting 240 into 288 lines, YUV 4 : 2 : 2)
- Vertical scaling, with phase accurate Linear Phase Interpolation (LPI) for zoom and down-scale, or phase accurate Accumulation Mode (ACM) for large down-scaling ratios and better alias suppression
- Variable Phase Delay (VPD), operates as horizontal phase accurate interpolation for arbitrary non-integer scaling ratios, supporting conversion between square (SQR) and rectangular (CCIR) pixel sampling
- Output formatter for scaled YUV 4 : 2 : 2, YUV 4 : 1 : 1 and Y only (format also for raw data)
- FIFO, 32-bit wide, with 64 pixel capacity in YUV formats
- Output interface, 8 or 16 (only if extended by H-port) data pins wide, synchronous or asynchronous operation, with stream events on discrete pins, or coded in the data stream.

The overall H and V zooming (HV\_zoom) is restricted by the input/output data rate relations. With a safety margin of 2% for running in and running out, the maximum HV\_zoom is equal to:

$$0.98 \times \frac{T_{\text{input\_field}} - T_{\text{v\_blanking}}}{\text{in\_pixel} \times \text{in\_lines} \times \text{out\_cycle\_per\_pix} \times T_{\text{out\_clk}}}$$

For example:

1. Input from decoder: 50 Hz, 720 pixel, 288 lines, 16-bit data at 13.5 MHz data rate, 1 cycle per pixel; output: 8-bit data at 27 MHz, 2 cycles per pixel; the maximum HV\_zoom is equal to:

$$0.98 \times \frac{20 \text{ ms} - 24 \times 64 \mu\text{s}}{720 \times 288 \times 2 \times 37 \text{ ns}} = 1.18$$

2. Input from X-port: 60 Hz, 720 pixel, 240 lines, 8-bit data at 27 MHz data rate (ITU 656), 2 cycles per pixel; output via I + H-port: 16-bit data at 27 MHz clock, 1 cycle per pixel; the maximum HV\_zoom is equal to:

$$0.98 \times \frac{16.666 \text{ ms} - 22 \times 64 \mu\text{s}}{720 \times 240 \times 1 \times 37 \text{ ns}} = 2.34$$

The video scaler receives its input signal from the video decoder or from the expansion port (X-port).

It gets 16-bit YUV 4 : 2 : 2 input data at a continuous rate of 13.5 MHz from the decoder. Discontinuous data stream can be accepted from the expansion port (X-port), normally 8-bit wide ITU 656 like YUV data, accompanied by a pixel qualifier on XDQ.

The input data stream is sorted into two data paths, one for luminance (or raw samples), and one for time multiplexed chrominance U and V samples. An YUV 4 : 1 : 1 input format is converted to 4 : 2 : 2 for the horizontal prescaling and vertical filter scaling operation.

The scaler operation is defined by two programming pages A and B, representing two different tasks, that can be applied field alternating or to define two regions in a field (e.g. with different scaling range, factors, and signal source during odd and even fields).

Each programming page contains control:

- For signal source selection and formats
- For task handling and trigger conditions
- For input and output acquisition window definition
- For H-prescaler, V-scaler and H-phase scaling.

## PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

Raw VBI-data will be handled as specific input format and need an own programming page (= own task).

In VBI pass through operation the processing of prescaler and vertical scaling has to be set to no-processing, but the horizontal fine scaling VPD can be activated. Upscaling (oversampling, zooming), free of frequency folding, up to factor 3.5 can be achieved, as required by some software data slicing algorithms.

These raw samples are transported through the image port as valid data and can be output as Y only format. The lines are framed by SAV and EAV codes.

### 8.3.1 ACQUISITION CONTROL AND TASK HANDLING (SUBADDRESSES 80H, 90H, 94H TO 9FH AND C4H TO CFH)

The acquisition control receives horizontal and vertical synchronization signals from the decoder section or from the X-port. The acquisition window is generated via pixel and line counters at the appropriate places in the data path. From X-port only qualified pixels and lines (= lines with qualified pixel) are counted.

The acquisition window parameters are:

- Signal source selection regarding input video stream and formats from the decoder, or from X-port (programming bits SCSRC[1:0]91H[5:4] and FSC[2:0]91H[2:0])
- Remark:** The input of raw VBI-data from internal decoder should be controlled via the decoder output formatter and the LCR registers (see Section 8.2 "Decoder output formatter")
- Vertical offset defined in lines of the video source, parameter YO[11:0]99H[3:0]98H[7:0]
  - Vertical length defined in lines of the video source, parameter YS[11:0]9BH[11:8]9AH[7:0]
  - Vertical length defined in number of target lines, as result of vertical scaling, parameter YD[11:0]9FH[11:8]9EH[7:0]
  - Horizontal offset defined in number of pixels of the video source, parameter XO[11:0]95H[3:0]94H[7:0]
  - Horizontal length defined in number of pixels of the video source, parameter XS[11:0]97H[3:0]96H[7:0]
  - Horizontal destination size, defined in target pixels after fine scaling, parameter XD[11:0]9DH[3:0]9CH[7:0].

The source start offset (XO11 to XO0, YO11 to YO0) opens the acquisition window, and the target size

(XD11 to XD0, YD11 to YD0) closes the window, but the window is cut vertically, if there are less output lines than expected. The trigger events for the pixel and line counts are the horizontal and vertical reference edges as defined in subaddress 92H.

The task handling is controlled by subaddress 90H (see Section 8.3.1.2).

#### 8.3.1.1 Input field processing

The trigger event for the field sequence detection from external signals (X-port) are defined in subaddress 92H. From the X-port the state of the scalers H-reference signal at the time of the V-reference edge is taken as field sequence identifier FID. For example, if the falling edge of the XRV input signal is the reference and the state of XRH input is logic 0 at that time, the detected field ID is logic 0.

The bits XFDV[92H[7]] and XFDH[92H[6]] are defining the detection event and state of the flag from the X-port. For the default setting of XFDV and XFDH at '00' the state of the H-input at the falling edge of the V-input is taken.

The scaler directly gets a corresponding field ID information from the SAA7114H decoder path.

The FID flag is used to determine, whether the first or second field of a frame is going to be processed within the scaler and it is used as trigger condition for the task handling (see bits STRC[1:0]90H[1:0]).

According to ITU 656, FID at logic 0 means first field of a frame. To ease the application, the polarities of the detection results on the X-port signals and the internal decoder ID can be changed via XFDH.

As the V-sync from the decoder path has a half line timing (due to the interlaced video signal), but the scaler processing only knows about full lines, during 1st fields from the decoder the line count of the scaler possibly shifts by one line, compared to the 2nd field. This can be compensated by switching the V-trigger event, as defined by XDVO, to the opposite V-sync edge or by using the vertical scalers phase offsets. The vertical timing of the decoder can be seen in Figs 21 and 22.

As the H and V reference events inside the ITU 656 data stream (from X-port) and the real-time reference signals from the decoder path are processed differently, the trigger events for the input acquisition also have to be programmed differently.

**Table 8** Processing trigger and start

DESCRIPTION	XDV1 92H[5]	XDV0 92H[4]	XDH 92H[2]
<b>Internal decoder:</b> The processing triggers at the falling edge of the V123 pulse (see Figs 21 (50 Hz) and 22 (60 Hz)), and starts earliest with the rising edge of the decoder HREF at line number: 4/7 (50/60 Hz, 1st field), respectively 3/6 (50/60 Hz, 2nd field) (decoder count) 2/5 (50/60 Hz, 1st field), respectively 2/5 (50/60 Hz, 2nd field) (decoder count)	0 0	1 0	0 0
<b>External ITU 656 stream:</b> The processing starts earliest with SAV at line number 23 (50 Hz system), respectively line 20 (60 Hz system) (according ITU 656 count)	0	0	0

### 8.3.1.2 Task handling

The task handler controls the switching between the two programming register sets. It is controlled by subaddresses 90H and C0H. A task is enabled via the global control bits TEA[80H[4]] and TEB[80H[5]].

The handler is then triggered by events, which can be defined for each register set.

In case of a programming error the task handling and the complete scaler can be reset to the initial states by the software reset bit SWRST[88H[5]] at logic 0.

Especially if the programming registers, related acquisition window and scale are reprogrammed, while a task is active, a software reset **must** be done after programming.

Contrary to the disabling/enabling of a task, which is evaluated at the end of a running task, SWRST at logic 0 sets the internal state machines directly to their idle states.

The start condition for the handler is defined by bits STRC[1:0]90H[1:0] and means: start immediately, wait for next V-sync, next FID at logic 0 or next FID at logic 1. The FID is evaluated, if the vertical and horizontal offsets are reached.

With RPTSK[90H[2]] at logic 1 the actual running task is repeated (under the defined trigger conditions), before handing control over to the alternate task.

To support field rate reduction, the handler is also enabled to skip fields (bits FSKP[2:0]90H[5:3]) before executing the task. A TOGGLE flag is generated (used for the correct output field processing), which changes state at the beginning of a task, every time a task is activated.

Examples can be seen in Section 8.3.1.3.

### Remarks:

- **To activate a task the start condition must be fulfilled and the acquisition window offsets must be reached.** For example, in case of 'start immediately', and two regions are defined for one field, the offset of the lower region must be greater than (offset + length) of upper region, if not, the actual counted H and V position at the end of the upper task is beyond the programmed offsets and the processing will 'wait for next V'.
- **Basically the trigger conditions are checked, when a task is activated.** It is important to realize, that they are not checked, while a task is inactive. So you can not trigger to next logic 0 or logic 1 with overlapping offset and active video ranges between the tasks (e.g. task A STRC[2:0] = 2, YO[11:0] = 310 and task B STRC[2:0] = 3, YO[11:0] = 310 results in output field rate of  $50\frac{2}{3}$  Hz).
- **After power-on or software reset (via SWRST[88H[5]]) task B gets priority over task A.**

---

**PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler**

---

**SAA7114H****8.3.1.3 Output field processing**

As reference for the output field processing, two signals are available for the back-end hardware.

These signals are the input field ID from the scaler source and a TOGGLE flag, which shows, that an active task is used an odd (1, 3, 5...) or even (2, 4, 6...) number of times. Using a single or both tasks and reducing the field or frame rate with the task handling functionality, the TOGGLE information can be used, to reconstruct an interlaced scaled picture at a reduced frame rate. The TOGGLE flag isn't synchronized to the input field detection, as it is only dependent on the interpretation of this information by the external hardware, whether the output of the scaler is processed correctly (see Section 8.3.3).

With OFIDC = 0, the scalers input field ID is available as output field ID on bit D6 of SAV and EAV, respectively on pin IGP0 (IGP1), if FID output is selected.

When OFIDC[90H[6]] = 1, the TOGGLE information is available as output field ID on bit D6 of SAV and EAV, respectively on pin IGP0 (IGP1), if FID output is selected.

Additionally the bit D7 of SAV and EAV can be defined via CONLH[90H[7]]. CONLH[90H[7]] = 0 (default) sets D7 to logic 1, a logic 1 inverts the SAV/EAV bit D7. So it's possible to mark the output of the both tasks by different SAV/EAV codes. This bit can also be seen as 'task flag' on the pins IGP0 (IGP1), if TASK output is selected.

**Notes**

1. Single task every field; OFIDC = 0; subaddress 90H at 40H; TEB[80H[5]] = 0.
2. Tasks are used to scale to different output windows, priority on task B after SWRST.
3. Both tasks at 1/2 frame rate; OFIDC = 0; subaddresses 90H at 43H and C0H at 42H.
4. In examples 3 and 4 the association between input FID and tasks can be flipped, dependent on which time the SWRST is de-asserted.
5. Task B at 2/3 frame rate constructed from neighbouring motion phases; task A at 1/3 frame rate of equidistant motion phases; OFIDC = 1; subaddresses 90H at 41H and C0H at 45H.
6. Task A and B at 1/3 frame rate of equidistant motion phases; OFIDC = 1; subaddresses 90H at 41H and C0H at 49H.
7. State of prior field.
8. It is assumed that input/output FID = 0 (= upper lines); UP = upper lines; LO = lower lines.
9. O = data output; NO = no output.

## PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

### 8.3.2 HORIZONTAL SCALING

The overall horizontal required scaling factor has to be split into a binary and a rational value according to the equation:

$$\text{H-scale ratio} = \frac{\text{output pixel}}{\text{input pixel}}$$

$$\text{H-scale ratio} = \frac{1}{\text{XPSC}[5:0]} \times \frac{1024}{\text{XSCY}[12:0]}$$

where, parameter of prescaler  $\text{XPSC}[5:0] = 1$  to 63 and parameter of VPD phase interpolation  $\text{XSCY}[12:0] = 300$  to 8191 (0 to 299 are only theoretical values). For example,  $\frac{1}{3.5}$  is to split in  $\frac{1}{4} \times 1.14286$ . The binary factor is processed by the prescaler, the arbitrary non-integer ratios is achieved via the variable phase delay VPD circuitry, called horizontal fine scaling. Latter calculates horizontally interpolated new samples with a 6-bit phase accuracy, which relates to less than 1 ns jitter for regular sampling scheme. Prescaler and fine scaler are building the horizontal scaler of the SAA7114H.

Using the accumulation length function of the prescaler ( $\text{XACL}[5:0]\text{A1H}[5:0]$ ), application and destination dependent (e.g. scale for display or for a compression machine), a compromise between visible bandwidth and alias suppression can be found.

#### 8.3.2.1 Horizontal prescaler (subaddresses A0H to A7H and D0H to D7H)

The prescaling function consists of an FIR anti-alias filter stage and an integer prescaler, which is building an adaptive prescale dependent low-pass filter, to balance sharpness and aliasing effects.

The FIR prefilter stage implements different low-pass characteristics to reduce alias for down-scales in the range of 1 to  $\frac{1}{2}$ . A CIF optimized filter is build in, which reduces artefacts for CIF output formats (to be used in combination with the prescaler set to  $\frac{1}{2}$  scale). See Table 10.

The functionality of the prescaler is defined by:

- An integer prescaling ratio  $\text{XPSC}[5:0]\text{A0H}[5:0]$  (= 1 to 63), which covers the integer down-scale range 1 to  $\frac{1}{63}$
- An averaging sequence length  $\text{XACL}[5:0]\text{A1H}[5:0]$  (= 0 to 63); range 1 to 64
- A DC gain renormalization  $\text{XDCG}[2:0]\text{A2H}[2:0]$ ; 1 down to  $\frac{1}{128}$

- The bit  $\text{XC2\_1}[\text{A2H}[3]]$ , which defines the weighting of the incoming pixels during the averaging process
  - $\text{XC2\_1} = 0 \Rightarrow 1 + 1 \dots + 1 + 1$
  - $\text{XC2\_1} = 1 \Rightarrow 1 + 2 \dots + 2 + 1$

The prescaler builds a prescale dependent FIR low-pass, with up to (64 + 7) filter taps. The parameter  $\text{XACL}[5:0]$  can be used to vary the low-pass characteristic for a given integer prescale of  $\frac{1}{\text{XPSC}[5:0]}$ . The user can therewith decide between signal bandwidth (= sharpness impression) and alias.

Equation for  $\text{XPSC}[5:0]$  calculation is:

$$\text{XPSC}[5:0] = \text{lower integer of } \frac{\text{Npix\_in}}{\text{Npix\_out}}$$

where,

the range is 1 to 63 (**value 0 is not allowed!**);

$\text{Npix\_in}$  = number of input pixel, and

$\text{Npix\_out}$  = number of desired output pixel over the complete horizontal scaler.

**The use of the prescaler results in a  $\text{XACL}[5:0]$  and  $\text{XC2\_1}$  dependent gain amplification.** The amplification can be calculated according to the equation:

$$\text{DC gain} = ((\text{XACL} - \text{XC2\_1}) + 1) \times (\text{XC2\_1} + 1)$$

It is recommended to use sequence lengths and weights, which results in a  $2^N$  DC gain amplification, as these amplitudes can be renormalized by the  $\text{XDCG}[2:0]$

controlled  $\frac{1}{2^N}$  shifter of the prescaler.

The renormalization range of  $\text{XDCG}[2:0]$  is 1,  $\frac{1}{2}$ ... down to  $\frac{1}{128}$ .

Other amplifications have to be normalized by using the following BCS control circuitry. In these cases the prescaler has to be set to an overall gain  $\leq 1$ , e.g. for an accumulation sequence of '1 + 1 + 1' ( $\text{XACL}[5:0] = 2$  and  $\text{XC2\_1} = 0$ ),  $\text{XDCG}[2:0]$  must be set to '010', equals  $\frac{1}{4}$  and the BCS has to amplify the signal to  $\frac{4}{3}$  ( $\text{SATN}[7:0]$  and  $\text{CONT}[7:0]$  value = lower integer of  $\frac{4}{3} \times 64$ ).

**The use of  $\text{XACL}[5:0]$  is  $\text{XPSC}[5:0]$  dependent.  $\text{XACL}[5:0]$  must be  $\leq 2 \times \text{XPSC}[5:0]$ .**

$\text{XACL}[5:0]$  can be used to find a compromise between bandwidth (= sharpness) and alias effects.

**PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler**

**SAA7114H**

**Remark:** Due to bandwidth considerations XPSC[5:0] and XACL[5:0] can be chosen different to the previous mentioned equations or Table 11, as the H-phase scaling is able to scale in the range from zooming up by factor 3 to down-scale by a factor of  $1024/8191$ .

Figs 26 and 27 show some resulting frequency characteristics of the prescaler.

Table 11 shows the recommended prescaler programming. Other programmings, than documented in Table 11, may result in better alias suppression, but the resulting DC gain amplification needs to be compensated by the BCS control, according to the equation:

$$CONT[7:0] = SATN[7:0] = \text{lower integer of } \frac{2^{XDG[2:0]}}{DC \text{ gain} \times 64}$$

Where:

$$2^{XDCG[2:0]} \geq DC \text{ gain}$$

$$DC \text{ gain} = (XC2\_1 + 1) \times XACL[5:0] + (1 - XC2\_1).$$

For example, if XACL[5:0] = 5, XC2\_1 = 1, then DC gain = 10 and the required XDCG[2:0] = 4.

The horizontal source acquisition timing and the prescaling ratio is identical for both luminance path and chrominance path, but the FIR filter settings can be defined differently in the two channels.

Fade-in and fade-out of the filters is achieved by copying an original source sample each as first and last pixel after prescaling.

Figs 24 and 25 show the frequency characteristics of the selectable FIR filters.

## PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

### 8.3.2.2 Horizontal fine scaling (variable phase delay filter; subaddresses A8H to AFH and D8H to DFH)

The horizontal fine scaling (VPD) should operate at scaling ratios between  $\frac{1}{2}$  and 2 (0.8 and 1.6), but can also be used for direct scale in the range from  $\frac{1}{7.999}$  to (theoretical) zoom 3.5 (restriction due to the internal data path architecture), without prescaler.

In combination with the prescaler a compromise between sharpness impression and alias can be found, which is signal source and application dependent.

For the luminance channel a filter structure with 10 taps is implemented, for the chrominance a filter with 4 taps.

Luminance and chrominance scale increments (XSCY[12:0]A9H[4:0]A8H[7:0] and XSCC[12:0]ADH[4:0]ACH[7:0]) are defined independently, but must be set in a 2 : 1 relation in the actual data path implementation. The phase offsets XPHY[7:0]AAH[7:0] and XPHC[7:0]AEH[7:0] can be used to shift the sample phases slightly. XPHY[7:0] and XPHC[7:0] covers the phase offset range  $7.999T$  to  $\frac{1}{32}T$ . The phase offsets should also be programmed in a 2 : 1 ratio.

The underlying phase controlling DTO has a 13-bit resolution.

According to the equations

$$XSCY[12:0] = 1024 \times \frac{N_{\text{pix\_in}}}{X_{\text{PSC}}} \times \frac{1}{N_{\text{pix\_out}}} \text{ and}$$

$$XSCC[12:0] = \frac{XSCY[12:0]}{2} \text{ the VPD covers the scale}$$

range from 0.125 to zoom 3.5. VPD acts equivalent to a polyphase filter with 64 possible phases. In combination with the prescaler, it is possible to get very accurate samples from a highly anti-aliased integer down-scaled input picture.

### 8.3.3 VERTICAL SCALING

The vertical scaler of the SAA7114H consists of a line FIFO buffer for line repetition and the vertical scaler block, which implements the vertical scaling on the input data stream in 2 different operational modes from theoretical zoom by 64 down to icon size  $\frac{1}{64}$ . The vertical scaler is located between the BCS and horizontal fine scaler, so that the BCS can be used to compensate the DC gain amplification of the ACM mode (see Section 8.3.3.2) as the internal RAMs are only 8-bit wide.

### 8.3.3.1 Line FIFO buffer (subaddresses 91H, B4H and C1H, E4H)

The line FIFO buffer is a dual ported RAM structure for 768 pixels, with asynchronous write and read access. The line buffer can be used for various functions, but not all functions may be available simultaneously.

The line buffer can buffer a complete unscaled active video line or more than one shorter lines (only for non-mirror mode), for selective repetition for vertical zoom-up.

For zooming up 240 lines to 288 lines e.g., every fourth line is requested (read) twice from the vertical scaling circuitry for calculation.

For conversion of a 4 : 2 : 0 or 4 : 1 : 0 input sampling scheme (MPEG, video phone, video YUV-9) to CCIR like sampling scheme 4 : 2 : 2, the chrominance line buffer is read twice of four times, before being refilled again by the source. By means of the input acquisition window definition it has to be preserved, that the processing starts with a line containing luminance and chrominance information for 4 : 2 : 0 and 4 : 1 : 0 input. The bits FSC[2:1]91H[2:1] are defining the distance between the Y/C lines. In case of 4 : 2 : 2 and 4 : 1 : 1 FSC2 to FSC1 have to be set to '00'.

The line buffer can also be used for mirroring, i.e. for flipping the image left to right, for the vanity picture in video phone application (bit YMIR[B4H[4]]). In mirror mode only one active prescaled line can be held in the FIFO at a time.

The line buffer can be utilized as excessive pipeline buffer for discontinuous and variable rate transfer conditions at expansion port or image port.

## PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

### 8.3.3.2 Vertical scaler (subaddresses B0H to BFH and E0H to EFH)

Vertical scaling of any ratio from 64 (theoretical zoom) to  $\frac{1}{63}$  (icon) can be applied.

The vertical scaling block consists of another line delay, and the vertical filter structure, that can operate in two different modes. Called linear interpolation (LPI) and accumulation (ACM) mode, controlled by YMODE[B4H[0]].

- **LPI mode:** In Linear Phase Interpolation (LPI) mode (YMODE = 0) two neighbouring lines of the source video stream are added together, but weighted by factors corresponding to the vertical position (phase) of the target output line relative to the source lines. This linear interpolation has a 6-bit phase resolution, which equals 64 intra line phases. It interpolates between two consecutive input lines only. LPI mode should be applied for scaling ratios around 1 (down to  $\frac{1}{2}$ ), **it must be applied for vertical zooming.**
- **ACM mode:** The vertical Accumulation (ACM) mode (YMODE = 1) represents a vertical averaging window over multiple lines, sliding over the field. This mode also generates phase correct output lines. The averaging window length corresponds to the scaling ratio, resulting in an adaptive vertical low-pass effect, to greatly reduce aliasing artefacts. ACM can be applied for down-scales only from ratio 1 down to  $\frac{1}{64}$ . ACM results in a scale dependent **DC gain amplification**, which has to be precorrected by the BCS control of the scaler part.

The phase and scale controlling DTO calculates in 16-bit resolution, controlled by parameters YSCY[15:0]B1H[7:0]B0H[7:0] and YSCC[15:0]B3H[7:0]B2H[7:0], continuously over the entire field. A start offset can be applied to the phase processing by means of the parameters YPY3[7:0] to YPY0[7:0] in BFH[7:0] to BCH[7:0] and YPC3[7:0] to YPC0[7:0] in BBH[7:0] to B8H[7:0]. The start phase covers the range of  $\frac{255}{32}$  to  $\frac{1}{32}$  lines offset.

By programming appropriate, opposite, vertical start phase values (subaddresses B8H to BFH and E8H to EFH) depending on odd/even field ID of the source video stream and A/B-page cycle, frame ID conversion

and field rate conversion are supported (i.e. de-interlacing, re-interlacing).

Figs 28 and 29 and Tables 12 and 13 are describing the use of the offsets.

**Remark: The vertical start phase, as well as scaling ratio are defined independently for luminance and chrominance channel, but must be set to the same values in the actual implementation for accurate 4 : 2 : 2 output processing.**

The vertical processing communicates on it's input side with the line FIFO buffer. The scale related equations are:

- Scaling increment calculation for ACM and LPI mode, down-scale and zoom:

$$YSCY(C)[15:0] = \text{lower integer of} \left( 1024 \times \frac{N_{\text{line\_in}}}{N_{\text{line\_out}}} \right)$$

- BCS value to compensate DC gain in ACM mode (contrast and saturation have to be set):  
CONT[7:0]A5H[7:0] respectively SATN[7:0]A6H[7:0]

$$= \text{lower integer of} \left( \frac{N_{\text{line\_out}}}{N_{\text{line\_in}}} \times 64 \right), \text{ or}$$

$$= \text{lower integer of} \left( \frac{1024}{YSCY[15:0]} \times 64 \right)$$

### 8.3.3.3 Use of the vertical phase offsets

As shown in Section 8.3.1.3, the scaler processing may run randomly over the interlaced input sequence. Additionally the interpretation and timing between ITU 656 field ID and real-time detection by means of the state of H-sync at falling edge of V-sync may result in different field ID interpretation.

Also a vertically scaled interlaced output gets a larger vertical sampling phase error, if the interlaced input fields are processed, without regarding the actual scale at the starting point of operation (see Fig.28).

Four events are to be considered, they are illustrated in Fig.29.

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

# PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

In Tables 12 and 13 **PHO** is a usable common phase offset.

Please notice that the equations of Fig.29 are producing an interpolated output also for the unscaled case, as the geometrical reference position for all conversions is the position of the first line of the lower field (see Table 12).

If there is no need for UP-LO and LO-UP conversion and the input field ID is the reference for the back-end operation, then it is UP-LO = UP-UP and LO-UP = LO-LO and the  $\frac{1}{2}$  line phase shift ( $PHO + 16$ ) can be skipped. This case is listed in Table 13.

The SAA7114H supports 4 phase offset registers per task and component (luminance and chrominance). The value of 20H represents a phase shift of one line.

The registers are assigned to the following events; e.g. subaddresses B8H to BBH:

- B8H: 00 = input field ID 0, task status bit 0 (toggle status, see Section 8.3.1.3)
- B9H: 01 = input field ID 0, task status bit 1
- BAH: 10 = input field ID 1, task status bit 0
- BBH: 11 = input field ID 1, task status bit 1.

Dependent on the input signal (interlaced or non-interlaced) and the task processing (50 Hz or field reduced processing with one or two tasks, see examples in Section 8.3.1.3), also other combinations may be possible, but the basic equations are the same.

**Table 12** Examples for vertical phase offset usage: global equations

INPUT FIELD UNDER PROCESSING	OUTPUT FIELD INTERPRETED AS	USED ABBREVIATION	EQUATION FOR PHASE OFFSET CALCULATION (DECIMAL VALUES)
Upper input lines	upper output lines	UP-UP	$PHO + 16$
Upper input lines	lower output lines	UP-LO	$PHO + \frac{YSCY[15:0]}{64} + 16$
Lower input lines	upper output lines	LO-UP	$PHO$
Lower input lines	Lower output lines	LO-LO	$PHO + \frac{YSCY[15:0]}{64}$

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler

SAA7114H

**Table 13** Vertical phase offset usage; assignment of the phase offsets

DETECTED INPUT FIELD ID	TASK STATUS BIT	VERTICAL PHASE OFFSET	CASE	EQUATION TO BE USED
0 = upper lines	0	YPY(C)0[7:0]	case 1 <sup>(1)</sup>	UP-UP (PHO)
			case 2 <sup>(2)</sup>	UP-UP
			case 3 <sup>(3)</sup>	UP-LO
0 = upper lines	1	YPY(C)1[7:0]	case 1	UP-UP (PHO)
			case 2	UP-LO
			case 3	UP-UP
1 = lower lines	0	YPY(C)2[7:0]	case 1	$LO-LO \left( PHO + \frac{YSCY[15:0]}{64} - 16 \right)$
			case 2	LO-UP
			case 3	LO-LO
1 = lower lines	1	YPY(C)3[7:0]	case 1	$LO-LO \left( PHO + \frac{YSCY[15:0]}{64} - 16 \right)$
			case 2	LO-LO
			case 3	LO-UP

**Notes**

- Case 1: OFIDC[90H[6]] = 0; scaler input field ID as output ID; back-end interprets output field ID at logic 0 as upper output lines.
- Case 2: OFIDC[90H[6]] = 1; task status bit as output ID; back-end interprets output field ID at logic 0 as upper output lines.
- Case 3: OFIDC[90H[6]] = 1; task status bit as output ID; back-end interprets output field ID at logic 1 as upper output lines.

# PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

## 8.4 VBI-data decoder and capture (subaddresses 40H to 7FH)

The SAA7114H contains a versatile VBI-data decoder.

The implementation and programming model accords to the VBI-data slicer built in the multimedia video data acquisition circuit SAA5284.

The circuitry recovers the actual clock phase during the clock run-in period, slices the data bits with the selected data rate, and groups them to bytes. The result is buffered into a dedicated VBI-data FIFO with a capacity of  $2 \times 56$  bytes ( $2 \times 14$  Dwords). The clock frequency, signals source, field frequency, accepted error count must be defined in subaddress 40H.

The supported VBI-data standards are shown in Table 14.

For lines 2 to 24 of a field, per VBI line, 1 of 16 standards can be selected (LCR24\_[7:0] to LCR2\_[7:0] in 57H[7:0] to 41H[7:0]:  $23 \times 2 \times 4$  bit programming bits).

The definition for line 24 is valid for the rest of the corresponding field, normally no text data (= video data) should be selected there (LCR24\_[7:0] = FFH) to stop the activity of the VBI-data slicer during active video.

To adjust the slicers processing to the input signal source, there are offsets in horizontal and vertical direction available: parameters HOFF[10:0]5BH[2:0]59H[7:0], VOFF[8:0]5BH[4]5AH[7:0] and FOFF[5BH[7]].

Contrary to the scalers counting, the slicers offsets are defining the position of the H and V trigger events related to the processed video field. The trigger events are the falling edge of HREF and the falling edge of V123 from the decoder processing part.

The relation of these programming values to the input signal and the recommended values can be seen in Tables 4 to 7.

**Table 14** Data types supported by the data slicer block

DT[3:0] 62H[3:0]	STANDARD TYPE	DATA RATE (Mbits/s)	FRAMING CODE	FC WINDOW	HAM CHECK

**PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler**

**SAA7114H**

**8.5 Image port output formatter (subaddresses 84H to 87H)**

The output interface consists of a FIFO for video and for sliced text data, an arbitration circuit, which controls the mixed transfer of video and sliced text data over the I-port and a decoding and multiplexing unit, which generates the 8 or 16-bit wide output data stream and the accompanied reference and supporting information.

The clock for the output interface can be derived from an internal clock, decoder, expansion port, or an externally provided clock which is appropriate for e.g. VGA and frame buffer. The clock can be up to 33 MHz. The scaler provides the following video related timing reference events (signals), which are available on pins as defined by subaddresses 84H and 85H:

- Output field ID
- Start and end of vertical active video range,
- Start and end of active video line
- Data qualifier or gated clock
- Actually activated programming page (if CONLH is used)
- Threshold controlled FIFO filling flags (empty, full, filled)
- Sliced data marker.

The disconnected data stream at the scaler output is accompanied by a data valid flag (or data qualifier), or is transported via a gated clock. Clock cycles with invalid data on the I-port data bus (including the HPD pins in 16-bit output mode) are marked with code 00H.

The output interface also arbitrates the transfer between scaled video data and sliced text data over the I-port output.

The bits VITX1 and VITX0 (subaddress 86H) are used to control the arbitration.

As further operation the serialization of the internal 32-bit Dwords to 8-bit or optional 16-bit output, as well as the insertion of the extended ITU 656 codes (SAV/EAV for video data, ANC or SAV/EAV codes for sliced text data) are done here.

For handshake with the VGA controller, or other memory or bus interface circuitry, programmable FIFO flags are provided (see Section 8.5.2).

**8.5.1 SCALER OUTPUT FORMATTER (SUBADDRESSES 93H AND C3H)**

The output formatter organizes the packing into the output FIFO. The following formats are available: YUV 4 : 2 : 2, YUV 4 : 1 : 1, YUV 4 : 2 : 0, YUV 4 : 1 : 0, Y only (e.g. for raw samples). The formatting is controlled by FSI[2:0]93H[2:0], FOI[1:0]93H[4:3] and FYSK[93H[5]].

The data formats are defined on Dwords, or multiples, and are similar to the video formats as recommended for PCI multimedia applications (compare SAA7146A), but planar formats are not supported.

FSI[2:0] defines the horizontal packing of the data, FOI[1:0] defines, how many Y only lines are expected, before a Y/C line will be formatted. If FYSK is set to logic 0 preceding Y only lines will be skipped, and output will always start with a Y/C line.

Additionally the output formatter limits the amplitude range of the video data (controlled by ILLV[85H[5]]); see Table 17.

**Table 15** Byte stream for different output formats

OUTPUT FORMAT	BYTE SEQUENCE FOR 8-BIT OUTPUT MODES													
YUV 4 : 2 : 2	C <sub>B0</sub>	Y0	C <sub>R0</sub>	Y1	C <sub>B2</sub>	Y2	C <sub>R2</sub>	Y3	C <sub>B4</sub>	Y4	C <sub>R4</sub>	Y5	C <sub>B6</sub>	Y6

LIMIT STEP ILLV[85H[5]]	VALID RANGE		SUPPRESSED CODES (HEXADECIMAL VALUE)	
	DECIMAL VALUE	HEXADECIMAL VALUE	LOWER RANGE	UPPER RANGE
0	1 to 254	01 to FE	00	FF
1	8 to 247	08 to F7	00 to 07	F8 to FF

## 8.5.2 VIDEO FIFO (SUBADDRESS 86H)

The video FIFO at the scaler output contains 32 Dwords. That corresponds to 64 pixels in 16-bit YUV 4 : 2 : 2 format. But as the entire scaler can act as pipeline buffer, the actually available buffer capacity for the image port is much higher, and can exceed beyond a video line.

The image port, and the video FIFO, can operate with the video source clock (synchronous mode) or with externally provided clock (asynchronous, and burst mode), as appropriate for the VGA controller or attached frame buffer.

The video FIFO provides 4 internal flags, reporting to which extent the FIFO is actually filled. These are:

- The FIFO Almost Empty (FAE) flag
- The FIFO Combined Flag (FCF) or FIFO filled, which is set at almost full level and reset, with hysteresis, only after the level crosses below the almost empty mark
- The FIFO Almost Full (FAF) flag
- The FIFO Overflow (FOVL) flag.

The trigger levels for FAE and FAF are programmable by FFL[1:0]86H[3:2] (16, 24, 28, full) and FEL[1:0]86H[1:0] (16, 8, 4, empty).

The state of this flag can be seen on the pins IGP0 or IGP1. The pin mapping is defined by subaddresses 84H and 85H (see Section 9.5).

## 8.5.3 TEXT FIFO

In the text FIFO the data of the terminal VBI-data slicer are collected before the transmission over the I-port is requested (normally before the video window starts). It is partitioned into two FIFO sections. A complete line is filled into the FIFO, before a data transfer is requested. So normally, one line text data is ready for transfer, while the next text line is collected. So sliced text data are delivered as a block of qualified data, without any qualification gaps in the byte stream of the I-port.

The decoded VBI-data is collected in the dedicated VBI-data FIFO. After capture of a line is completed, the FIFO can be streamed through the image port, preceded by a header, telling line number and standard.

The VBI-data period can be signalled via the sliced data flag on pin IGP0 or IGP1. The decoded VBI-data is lead by the ITU ancillary data header (DID[5:0]5DH[5:0] at value <3EH) or by SAV/EAV codes selectable by DID[5:0] at value 3EH or 3FH. IGP0 or IGP1 is set, if the first byte of the ANC header is valid on the I-port bus. It is reset, if an SAV occurs. So it may frame multiple lines of text data output, in case video processing starts with a distance of several video lines to the region of text data. Valid sliced data from the text FIFO are available on the I-port as long as the IGP0 or IGP1 flag is set and the data qualifier is active on pin IDQ.

The decoded VBI-data are presented in two different data formats, controlled by bit RECODE.

- RECODE = 1: values 00H and FFH will be recoded to even parity values 03H and FCH
- RECODE = 0: values 00H and FFH may occur in the data stream as detected.

## 8.5.4 VIDEO AND TEXT ARBITRATION (SUBADDRESS 86H)

Sliced text data and scaled video data are transferred over the same bus, the I-port. The mixed transfer is controlled by an arbitration circuitry. If the video data are transferred without any interrupt and the video FIFO does not need to buffer any output pixel, the text data are inserted after an end of a scaled video line, normally during the blanking interval of the video.

# PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

## 8.5.5 DATA STREAM CODING AND REFERENCE SIGNAL GENERATION (SUBADDRESSES 84H, 85H AND 93H)

As H and V reference signals are logic 1, active gate signals are generated, which are framing the transfer of the valid output data. Alternative to the gates, H and V trigger pulses are generated on the rising edges of the gates.

Due to the dynamic FIFO behaviour of the complete scaler path, the output signal timing has no fixed timing relation to the real-time input video stream. So fixed propagation delays, in terms of clock cycles, related to the analog input can not be defined.

The data stream is accompanied by a data qualifier. Additionally invalid data cycles are marked with code 00H.

If ITU 656 like codes are not wanted, these codes can be suppressed in the output stream.

As further option, it is possible to provide the scaler with a gating external signal on pin ITRDY. So it is possible to hold the data output for a certain time and to get valid output data in bursts of a guaranteed length.

The sketched reference signals and events can be mapped to the I-port output pins IDQ, IGP0, IGP1, IGPV, IGPV and IGPV. For flexible use the polarities of all the outputs can be modified. The default polarity for the qualifier and reference signals is logic 1 (= active).

Table 18 shows the relevant and supported SAV and EAV coding.

**Table 18** SAV/EAV codes on I-port

EVENT DESCRIPTION	SAV/EAV CODES ON I-PORT <sup>(1)</sup> (HEX)				COMMENT
	MSB <sup>(2)</sup> OF SAV/EAV BYTE = 0		MSB <sup>(2)</sup> OF SAV/EAV BYTE = 1		
	FIELD ID = 0	FIELD ID = 1	FIELD ID = 0	FIELD ID = 1	
Next pixel is FIRST pixel of any active line	0E	49	80	C7	HREF = active; VREF = active
Previous pixel was LAST pixel of any active line, but not the last	13	54	9D	DA	HREF = inactive; VREF = active
Next pixel is FIRST pixel of any V-blanking line	25	62	AB	EC	HREF = active; VREF = inactive
Previous pixel was LAST pixel of the last active line or of any V-blanking line	38	7F	B6	F1	HREF = inactive; VREF = inactive
No valid data, don't capture and don't increment pointer	00				IDQ pin inactive

### Notes

- The leading byte sequence is: FFH-00H-00H.
- The MSB of the SAV/EAV code byte is controlled by:
  - Scaler output data: task A  $\Rightarrow$  MSB =  $\overline{\text{CONLH}}$  (90H[7]); task B  $\Rightarrow$  MSB =  $\overline{\text{CONLH}}$  (C0H[7]).
  - VBI-data slicer output data: DID[5:0]5DH[5:0] = 3EH  $\Rightarrow$  MSB = 1; DID[5:0]5DH[5:0] = 3FH  $\Rightarrow$  MSB = 0.

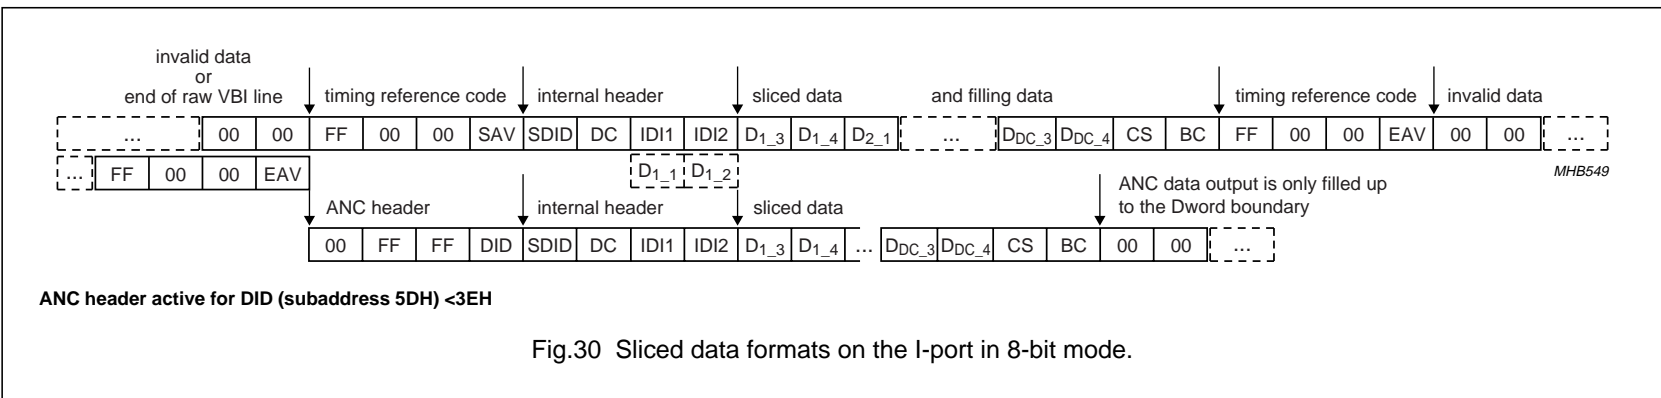

Fig.30 Sliced data formats on the I-port in 8-bit mode.

Table 19 Explanation to Fig.30

NAME	EXPLANATION
SAV	start of active data; see Table 20
SDID	sliced data identification: NEP <sup>(1)</sup> , EP <sup>(2)</sup> , SDID5 to SDID0, freely programmable via I <sup>2</sup> C-bus subaddress 5EH, D5 to D0, e. g. to be used as source identifier
DC	Dword count: NEP <sup>(1)</sup> , EP <sup>(2)</sup> , DC5 to DC0. DC describes the number of succeeding 32-bit words: <ul style="list-style-type: none"> <li>For SAV/EAV mode DC is fixed to 11 Dwords (byte value 4BH)</li> <li>For ANC mode it is: <math>DC = \frac{1}{4}(C + n)</math>, where <math>C = 2</math> (the two data identification bytes IDI1 and IDI2) and <math>n =</math> number of decoded bytes according to the chosen text standard.</li> </ul> Note that the number of valid bytes inside the stream can be seen in the BC byte.
IDI1	internal data identification 1: OP <sup>(3)</sup> , FID (field 1 = 0, field 2 = 1), LineNumber8 to LineNumber3 = Dword 1 byte 1; see Table 20
IDI2	internal data identification 2: OP <sup>(3)</sup> , LineNumber2 to LineNumber0, DataType3 to DataType0 = Dword 1 byte 2; see Table 20
D <sub>n_m</sub>	Dword number <b>n</b> , byte number <b>m</b>
D <sub>DC_4</sub>	last Dword byte 4, note: for SAV/EAV framing DC is fixed to 0BH, missing data bytes are filled up; the fill value is A0H
CS	the check sum byte, the checksum is accumulated from the SAV (respectively DID) byte to the D <sub>DC_4</sub> byte
BC	number of valid sliced bytes counted from the IDI1 byte
EAV	end of active data; see Table 20

Notes

1. Inverted EP (bit 7); for EP see note 2.
2. Even parity (bit 6) of bits 5 to 0.
3. Odd parity (bit 7) of bits 6 to 0.

SAA7114H

## 8.6 Audio clock generation (subaddresses 30H to 3FH)

SAA7114H incorporates generation of a field locked audio clock, as an auxiliary function for video capture. An audio sample clock, that is locked to the field frequency, makes sure that there is always the same predefined number of audio samples associated with a field, or a set of fields. That ensures synchronous playback of audio and video after digital recording (e.g. capture to hard disk), MPEG or other compression, or non-linear editing.

### 8.6.1 MASTER AUDIO CLOCK

The audio clock is synthesized from the same crystal frequency as the line-locked video clock is generated. The master audio clock is defined by the parameters:

- Audio master Clocks Per Field, ACPF[17:0]32H[1:0]31H[7:0]30H[7:0] according to the equation:  $ACPF[17:0] = \text{round}\left(\frac{\text{audio frequency}}{\text{field frequency}}\right)$

- Audio master Clocks Nominal Increment, ACNI[21:0]36H[5:0]35H[7:0]34H[7:0] according to the equation:  $ACNI[21:0] = \text{round}\left(\frac{\text{audio frequency}}{\text{crystal frequency}} \times 2^{23}\right)$

See Table 21 for examples.

**Remark:** For standard applications the synthesized audio clock AMCLK can be used directly as master clock and as input clock for port AMXCLK (short cut) to generate ASCLK and ALRCLK. For high-end applications it is recommended to use an external analog PLL circuit to enhance the performance of the generated audio clock.

**Table 21** Programming examples for audio master clock generation

XTALO (MHz)	FIELD (Hz)	ACPF		ACNI	
		DECIMAL	HEX	DECIMAL	HEX
<b>AMCLK = 256 × 48 kHz (12.288 MHz)</b>

**PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler**

**SAA7114H**

**8.6.2 SIGNALS ASCLK AND ALRCLK**

Two binary divided signals ASCLK and ALRCLK are provided for slower serial digital audio signal transmission and for channel-select. The frequencies of these signals are defined by the parameters:

- SDIV[5:0]38H[5:0] according to the equation:

$$f_{ASCLK} = \frac{f_{AMXCLK}}{(SDIV + 1) \times 2} \Rightarrow SDIV[5:0] = \frac{f_{AMXCLK}}{2f_{ASCLK}} - 1$$

- LRDIV[5:0]39H[5:0] according to the equation:

$$f_{ALRCLK} = \frac{f_{ASCLK}}{LRDIV \times 2} \Rightarrow LRDIV[5:0] = \frac{f_{ASCLK}}{2f_{ALRCLK}}$$

See Table 22 for examples.

**Table 22** Programming examples for ASCLK/ALRCLK clock generation

AMXCLK (MHz)	ASCLK (kHz)	SDIV		ALRCLK (kHz)	LRDIV	
		DECIMAL	HEX		DECIMAL	HEX
12.288	1536	3	03	48	16	10
	768	7	07		8	08
11.2896	1411.2	3	03	44.1	16	10

SAA7114H

## 9 INPUT/OUTPUT INTERFACES AND PORTS

The SAA7114H has 5 different I/O interfaces:

- Analog video input interface, for analog CVBS and/or Y and C input signals
- Audio clock port
- Digital real-time signal port (RT port)
- Digital video expansion port (X-port), for unscaled digital video input and output
- Digital image port (I-port) for scaled video data output and programming
- Digital host port (H-port) for extension of the image port or expansion port from 8 to 16-bit.

### 9.1 Analog terminals

The SAA7114H has 6 analog inputs AI21 to AI24, AI11 and AI12 for composite video CVBS or S-video Y/C signal pairs. Additionally, there are two differential reference inputs, which must be connected to ground via a capacitor equivalent to the decoupling capacitors at the 6 inputs. There are no peripheral components required other than these decoupling capacitors and 18  $\Omega$ /56  $\Omega$  termination resistors, one set per connected input signal (see also application example in Fig.40). Two anti-alias filters are integrated, and self adjusting via the clock frequency.

Clamp and gain control for the two ADC's are also integrated. An analog video output pin AOUT is provided for testing purposes.

**Table 23** Analog pin description

SYMBOL	PIN	I/O	DESCRIPTION	BIT
AI24 to AI21	10, 12, 14 and 16	I	analog video signal inputs, e.g. 2 CVBS signals and two Y/C pairs can be connected simultaneously	MODE3 to MODE0
AI12 and AI11	18 and 20			
AOUT	22	O	analog video output, for test purposes	AOSL1 and AOSL0
AI1D and AI2D	19 and 13	I	analog reference pins for differential ADC operation	–

### 9.2 Audio clock signals

The SAA7114H also synchronizes the audio clock and sampling rate to the video frame rate, via a very slow PLL. This ensures that the multimedia capture and compression processes always gather the same predefined number of samples per video frame.

An audio master clock AMCLK and two divided clocks ASCLK and ALRCLK are generated;

- ASCLK: can be used as audio serial clock
- ALRCLK: audio left/right channel clock.

The ratios are programmable, see also Section 8.6.

**Table 24** Audio clock pin description

SYMBOL	PIN	I/O	DESCRIPTION	BIT
AMCLK	37	O	audio master clock output	ACPF[17:0]32H[1:0]31H[7:0]30H[7:0] and ACNI[21:0]36H[5:0]35H[7:0]34H[7:0]
AMXCLK	41	I	external audio master clock input for the clock division circuit, can be directly connected to output AMCLK for standard applications	–
ASCLK	39	O	serial audio clock output, can be synchronized to rising or falling edge of AMXCLK	SDIV[5:0]38H[5:0] and SCPH[3AH[0]]
ALRCLK	40	O	audio channel (left/right) clock output, can be synchronized to rising or falling edge of ASCLK	LRDIV[5:0]39H[5:0] and LRPH[3AH[1]]

# PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

## 9.3 Clock and real-time synchronization signals

For the generation of the line-locked video (pixel) clock LLC, and of the frame locked audio serial bit clock, a crystal accurate frequency reference is required. An oscillator is built in, for fundamental or third harmonic crystals. The supported crystal frequencies are 32.11 or 24.576 MHz (defined during reset by strapping pin ALRCLK).

Alternatively pin XTALI can be driven from an external single ended oscillator.

The crystal oscillation can be propagated as clock to other ICs in the system via pin XOUT.

The Line-Locked Clock (LLC) is the double pixel clock of nominal 27 MHz. It is locked to the selected video input, generating baseband video pixels according to "ITU recommendation 601". In order to support interfacing circuitries, a direct pixel clock LLC2 is also provided.

The pins for line and field timing reference signals are RTCO, RTS1 and RTS0. Various real-time status information can be selected for the RTS pins. The signals are always available (output) and reflect the synchronization operation of the decoder part in the SAA7114H. The function of the RTS1 and RTS0 pins can be defined by bits RTSE1[3:0]12H[7:4] and RTSE0[3:0]12H[3:0].

**Table 25** Clock and real-time synchronization signals

SYMBOL	PIN	I/O	DESCRIPTION	BIT
<b>Crystal oscillator</b>				
XTALI	7	I	input for crystal oscillator, or reference clock	–
XTALO	6	O	output of crystal oscillator	–
XOUT	4	O	reference (crystal) clock output drive (optional)	XTOUTE[14H[3]]
<b>Real-time signals (RT port)</b>				
LLC	28	O	line-locked clock, nominal 27 MHz, double pixel clock locked to the selected video input signal	–
LLC2	29	O	line-locked pixel clock, nominal 13.5 MHz	–
RTCO	36	O	real-time control output, transfers real-time status information supporting RTC level 3.1 (see external document "RTC Functional Description", available on request)	–
RTS0	34	O	real-time status information line 0, can be programmed to carry various real-time informations (see Table 55)	RTSE0[3:0]12H[3:0]
RTS1	35	O	real-time status information line 1, can be programmed to carry various real-time informations (see Table 56)	RTSE1[3:0]12H[7:4]

# PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

## 9.4 Video expansion port (X-port)

The expansion port is intended for transporting video streams image data from other digital video circuits like MPEG encoder/decoder and video phone codec, to the image port (I-port).

The expansion port consists of two groups of signals/pins:

- 8-bit data, I/O, regularly components video YUV 4 : 2 : 2, i.e. C<sub>B</sub>-Y-C<sub>R</sub>-Y, byte serial, exceptionally raw video samples (e.g. ADC test). In input mode the data bus can be extended to 16-bit by the pins HPD7 to HPD0.
- Clock, synchronization and auxiliary signals, accompanying the data stream, I/O.

As output, these are direct copies of the decoder signals.

The data transfers through the expansion port represent a single D1 port, with half duplex mode. The SAV and EAV codes may be inserted optionally for data input (controlled by bit XCODE[92H[3]]). The input/output direction is switched for complete fields, only.

**Table 26** Signals dedicated to the expansion port

SYMBOL	PIN	I/O	DESCRIPTION	BIT
XPD7 to XPD0	81, 82, 84 to 87, 89 and 90	I/O	X-port data: in output mode controlled by decoder section, data format see Table 27; in input mode YUV 4 : 2 : 2 serial input data or luminance part of a 16-bit YUV 4 : 2 : 2 input	OFTS[2:0]13H[2:0]; 91H[7:0] and C1H[7:0]
XCLK	94	I/O	clock at expansion port: if output, then copy of LLC; as input normally a double pixel clock of up to 32 MHz or a gated clock (clock gated with a qualifier)	XCKS[92H[0]]
XDQ	95	I/O	data valid flag of the expansion port input (qualifier): if output, then decoder (HREF and VGATE) gate (see Fig.23)	–
XRDY	96	O	data request flag = ready to receive, to work with optional buffer in external device, to prevent internal buffer overflow; second function: input related task flag A/B	XRQT[83H[2]]
XRH	92	I/O	horizontal reference signal for the X-port: as output: HREF or HS from the decoder (see Fig.23); as input: a reference edge for horizontal input timing and a polarity for input field ID detection can be defined	XRHS[13H[6]], XFDH[92H[6]] and XDH[92H[2]]
XRV	91	I/O	vertical reference signal for the X-port: as output: V123 or field ID from the decoder, see Figs 21 and 22; as input: a reference edge for vertical input timing and for input field ID detection can be defined	XRVS[1:0]13H[5:4], XFDV[92H[7]] and XDV[1:0]92H[5:4]
XTRI	80	I	port control: switches X-port input 3-state	XPE[1:0]83H[1:0]

**PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler**

**SAA7114H**

9.4.1 X-PORT CONFIGURED AS OUTPUT

If data output is enabled at the expansion port, then the data stream from the decoder is presented. The data format of the 8-bit data bus is dependent on the chosen data type, selectable by the line control registers LCR2 to LCR24; see Table 3. In contrast to the image port, the sliced data format is not available on the expansion port. Instead, raw CVBS samples are always transferred if any sliced data type is selected.

Following are some details of data types on the expansion port:

- **Active video** (data type 15) contains component YUV 4 : 2 : 2 signal, 720 active pixels per line. The amplitude and offsets are programmable via DBR17 to DBR10, DCON7 to DCON0, DSAT7 to DSAT0, OFFU1, OFFU0, OFFV1 and OFFV0. For nominal levels see Fig.17.
- **Test line** (data type 6) is similar to active video format, with some constraints within the data processing:
  - adaptive chrominance comb filter, vertical filter (chrominance comb filter for NTSC standards, PAL phase error correction) within the chrominance processing are disabled
  - adaptive luminance comb filter, peaking and chrominance trap are bypassed within the luminance processing.

This data type is defined for future enhancements. It could be activated for lines containing standard test signals within the vertical blanking period. Currently the most sources do not contain test lines. For nominal levels see Fig.17.
- **Raw samples** (data types 0 to 5 and 7 to 14): UV-samples are similar to data type 6, but CVBS samples are transferred instead of processed luminance samples within the Y time slots.

The amplitude and offset of the CVBS signal is programmable via RAWG7 to RAWG0 and RAWO7 to RAWO0; see Chapter 15 “I<sup>2</sup>C-bus description”, Tables 62 and 63. For nominal levels see Fig.18.

The relation of LCR programming to line numbers is described in Section 8.2, see Tables 4 to 7.

The data type selections by LCR are overruled by setting OFTS2 (subaddress 13H bit 2) = 1. This setting is mainly intended for device production test. The VPO-bus carries the upper or lower 8 bits of the two ADCs dependent on OFTS[1:0]13H[1:0] settings; see Table 57. The output configuration is done via MODE[3:0]02H[3:0] settings; see Table 39. If a YC mode is selected, the expansion port carries the multiplexed output signals of both ADCs, in CVBS mode the output of only one ADC. No timing reference codes are generated in this mode.

**Remark:** The LSBs (bit 0) of the ADCs are also available on pin RTS0. For details see Table 55.

The SAV/EAV timing reference codes define start and end of valid data regions. During horizontal blanking period between EAV and SAV the ITU-blanking code sequence ‘- 80 - 10 - 80 - 10 -...’ is transmitted.

The position of the F-bit is constant according to ITU 656 (see Tables 29 and 30).

The V-bit can be generated in two different ways (see Tables 29 and 30) controlled via OFTS1 and OFTS0, see Table 57.

F and V bits change synchronously with the EAV code.

**Table 27** Data format on the expansion port

BLANKING PERIOD			TIMING REFERENCE CODE (HEX) <sup>(1)</sup>				720 PIXELS YUV 4 : 2 : 2 DATA <sup>(2)</sup>								TIMING REFERENCE CODE (HEX) <sup>(1)</sup>			BLANKING PERIOD				
...	80	10	FF	00	00	SAV	C <sub>B0</sub>	Y <sub>0</sub>	C <sub>R0</sub>	Y <sub>1</sub>	C <sub>B2</sub>	Y <sub>2</sub>	...	C <sub>R18</sub>	Y <sub>19</sub>	FF	00	00	EAV	80	10	...

**Notes**

1. The generation of the timing reference codes can be suppressed by setting OFTS[2:0] to ‘010’, see Table 57. In this event the code sequence is replaced by the standard ‘- 80 - 10 -’ blanking values.
2. If raw samples or sliced data are selected by the line control registers (LCR2 to LCR24), the Y-samples are replaced by CVBS samples.

## PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

### 9.4.2 X-PORT CONFIGURED AS INPUT

If data input mode is selected at the expansion port, then the scaler can choose its input data stream from the on-chip video decoder, or from expansion port (controlled by bit SCSRC[1:0]91H[5:4]). Byte serial YUV 4 : 2 : 2, or subsets for other sampling schemes, or raw samples from an external ADC may be input (see also bits FSC[2:0]91H[2:0]). The input stream must be accompanied by an external clock XCLK, qualifier XDQ and reference signals XRH and XRV. Instead of the reference signal, embedded SAV and EAV codes according to ITU 656 are also accepted. The protection bits are not evaluated.

XRH and XRV carry the horizontal and vertical synchronization signals for the digital video stream through the expansion port. The field ID of the input video stream is carried in the phase (edge) of XRV and state of XRH, or directly as FS (frame sync, odd/even signal) on the XRV pin (controlled by XFDV[92H[7]], XFDH[92H[6]] and XDV1[92H[5]]).

The trigger events on XRH (rising/falling edge) and XRV (rising/falling/both edges) for the scalers acquisition window are defined by XDV[1:0]92H[5:4] and XDH[92H[2]]. Also the signal polarity of the qualifier can be defined (bit XDQ[92H[1]]). Alternatively to a qualifier, the input clock can be applied to a gated clock (means clock gated with a data qualifier, controlled by bit XCKS[92H[0]]). In this event, all input data will be qualified.

### 9.5 Image port (I-port)

The image port transfers data from the scaler as well as from the VBI-data slicer, if so selected (maximum 33 MHz). The reference clock is available at the ICLK pin, as output, or as input (maximum 33 MHz). As output, ICLK is derived from the locked decoder or expansion port input clock. The data stream from the scaler output is normally discontinuous. Therefore valid data during a clock cycle is accompanied by a data qualifying (data valid) flag on pin IDQ. For pin constrained applications the IDQ pin can be programmed to function as gated clock output (bit ICKS2[80H[2]]).

The data formats at the image port are defined in Dwords of 32 bits (4 bytes), like the related FIFO structures. But the physical data stream at the image port is only 16-bit or 8-bit wide; in 16-bit mode data pins HPD7 to HPD0 are used for chrominance data. The four bytes of the Dwords are serialized in words or bytes.

Available formats are:

- YUV 4 : 2 : 2,
- YUV 4 : 1 : 1,
- Raw samples
- Decoded VBI-data.

For handshake with the receiving VGA controller, or other memory or bus interface circuitry, F, H and V reference signals and programmable FIFO flags are provided. The information will be provided on pins IGP0, IGP1, IGPH and IGPV. The functionality on this pins is controlled via subaddresses 84H and 85H.

VBI-data is collected over an entire line in its own FIFO, and transferred as an uninterrupted block of bytes. Decoded VBI-data can be signed by the VBI flag on pin IGP0/1.

As scaled video data and decoded VBI-data may come from different and asynchronous sources, an arbitration scheme is needed. Normally VBI-data slicer has priority.

The image port consists of the pins and/or signals, as listed in Table 31.

For pin constrained applications, or interfaces, the relevant timing and data reference signals can also get encoded into the data stream. Therefore the corresponding pins do not need to get connected. The minimum image port configuration requires 9 pins only, i.e. 8 pins for data including codes, and 1 pin for clock or gated clock. The inserted codes are defined in close relation to the ITU/CCIR-656 (D1) recommendation, where possible.

The following deviations from "ITU 656 recommendation" are implemented at SAA7114H's image port interface:

- SAV and EAV codes are only present in those lines, where data is to be transferred, i.e. active video lines, or VBI-raw samples, no codes for empty lines
- There may be more or less than 720 pixels between SAV and EAV
- Data content and number of clock cycles during horizontal and vertical blanking is undefined, and may be not constant
- Data stream may be interleaved with not-valid data codes, 00H, but SAV and EAV 4-byte codes are not interleaved with not-valid data codes
- There may be an irregular pattern of not-valid data, or IDQ, and as a result, 'C<sub>B</sub> - Y - C<sub>R</sub> - Y - ' is not in a fixed phase to a regular clock divider

# PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

- VBI-raw sample streams are enveloped with SAV and EAV, like normal video
- Decoded VBI-data is transported as Ancillary (ANC) data, two modes:
  - direct decoded VBI-data bytes (8-bit) are directly placed in the ANC data field, 00H and FFH codes may appear in data block (violation to CCIR-656)
  - recoded VBI-data bytes (8-bit) directly placed in ANC data field, 00H and FFH codes will be recoded to even parity codes 03H and FCH to suppress invalid CCIR-656 codes.

There are no empty cycles in the ancillary code and its data field. The data codes 00H and FFH are suppressed (changed to 01H or FEH respectively) in active video stream, as well as in VBI-raw sample stream (VBI pass-through). Optionally the number range can be limited further.

**Table 31** Signals dedicated to the image port

SYMBOL	PIN	I/O	DESCRIPTION	BIT
IPD7 to IPD0	54 to 57 and 59 to 62	I/O	I-port data	ICODE[93H[7]], ISWP[1:0]85H[7:6] and IPE[1:0]87[1:0]

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

9.6 Host port for 16-bit extension of video data I/O (H-port)

The H-port pins HPD can be used for extension of the data I/O paths to 16-bit.

Functional priority has the I-port. If I8\_16[93H[6]] is set to logic 1 the output drivers of the H-port are enabled dependent on the I-port enable control. For I8\_16 = 0, the HPD output is disabled.

Table 32 Signals dedicated to the host port

SYMBOL	PIN	I/O	DESCRIPTION	BIT
HPD7 to HPD0	64 to 67 and 69 to 72	I/O	16-bit extension for digital I/O (chrominance component)	IPE[1:0]87H[1:0], ITRI[8FH[6]] and I8_16[93H[6]]

9.7 Basic input and output timing diagrams I-port and X-port

9.7.1 I-PORT OUTPUT TIMING

The following diagrams are sketching the output timing via the I-port. IGPH and IGPV are sketched as logic 1 active gate signals. If reference pulses are programmed, these pulses are generated on the rising edge of the logic 1 active gates. Valid data is accompanied by the output data qualifier on pin IDQ. In addition invalid cycles are marked with output code 00H.

The IDQ output pin may be defined to be a gated clock output signal (ICLK AND internal IDQ).

9.7.2 X-PORT INPUT TIMING

At the X-port the input timing requirements are the same as sketched for the I-port output. But different to this:

- It is not necessary to mark invalid cycles with a 00H code
- No constraints on the input qualifier (can be a random pattern)
- XCLK may be a gated clock (XCLK AND external XDQ).

**Remark:** All timings illustrated in Figs 31 to 37 are given for an uninterrupted output stream (no handshake with the external hardware).

SAA7114H

## 10 BOUNDARY SCAN TEST

The SAA7114H has built in logic and 5 dedicated pins to support boundary scan testing which allows board testing without special hardware (nails). The SAA7114H follows the "IEEE Std. 1149.1 - Standard Test Access Port and Boundary-Scan Architecture" set by the Joint Test Action Group (JTAG) chaired by Philips.

The 5 special pins are Test Mode Select (TMS), Test Clock (TCK), Test Reset ( $\overline{\text{TRST}}$ ), Test Data Input (TDI) and Test Data Output (TDO).

The Boundary Scan Test (BST) functions BYPASS, EXTEST, INTEST, SAMPLE, CLAMP and IDCODE are all supported (see Table 33). Details about the JTAG BST-TEST can be found in the specification "IEEE Std. 1149.1". A file containing the detailed Boundary Scan Description Language (BSDL) description of the SAA7114H is available on request.

**Table 33** BST instructions supported by the SAA7114H

INSTRUCTION	DESCRIPTION
BYPASS	This mandatory instruction provides a minimum length serial path (1 bit) between TDI and TDO when no test operation of the component is required.
EXTEST	This mandatory instruction allows testing of off-chip circuitry and board level interconnections.
SAMPLE	This mandatory instruction can be used to take a sample of the inputs during normal operation of the component. It can also be used to preload data values into the latched outputs of the boundary scan register.
CLAMP	This optional instruction is useful for testing when not all ICs have BST. This instruction addresses the bypass register while the boundary scan register is in external test mode.
IDCODE	This optional instruction will provide information on the components manufacturer, part number and version number.
INTEST	This optional instruction allows testing of the internal logic (no customer support available).
USER1	This private instruction allows testing by the manufacturer (no customer support available).

### 10.1 Initialization of boundary scan circuit

The TAP (Test Access Port) controller of an IC should be in the reset state (TEST\_LOGIC\_RESET) when the IC is in functional mode. This reset state also forces the instruction register into a functional instruction such as IDCODE or BYPASS.

To solve the power-up reset, the standard specifies that the TAP controller will be forced asynchronously to the TEST\_LOGIC\_RESET state by setting the  $\overline{\text{TRST}}$  pin LOW.

### 10.2 Device identification codes

A device identification register is specified in "IEEE Std. 1149.1b-1994". It is a 32-bit register which contains fields for the specification of the IC manufacturer, the IC part number and the IC version number. Its biggest advantage is the possibility to check for the correct ICs mounted after production and determination of the version number of ICs during field service.

When the IDCODE instruction is loaded into the BST instruction register, the identification register will be connected between TDI and TDO of the IC. The identification register will load a component specific code during the CAPTURE\_DATA\_REGISTER state of the TAP controller and this code can subsequently be shifted out. At board level this code can be used to verify component manufacturer, type and version number. The device identification register contains 32 bits, numbered 31 to 0, where bit 31 is the most significant bit (nearest to TDI) and bit 0 is the least significant bit (nearest to TDO); see Fig.38.

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

Fig.38 32 bits of identification code.

**11 LIMITING VALUES**

In accordance with the Absolute Maximum Rating System (IEC 134); all ground pins connected together and all supply pins connected together.

SYMBOL	PARAMETER	CONDITIONS	MIN.	MAX.	UNIT
V <sub>DDD</sub>	digital supply voltage		-0.5	+4.6	V
V <sub>DDA</sub>	analog supply voltage		-0.5	+4.6	V
V <sub>IA</sub>	input voltage at analog inputs		-0.5	V <sub>DDA</sub> + 0.5 <sup>(1)</sup>	V
V <sub>OA</sub>	output voltage at analog output		-0.5	V <sub>DDA</sub> + 0.5	V
V <sub>ID</sub>	input voltage at digital inputs and outputs	outputs in 3-state; note 2	-0.5	+5.5	V
V <sub>OD</sub>	output voltage at digital outputs	outputs active	-0.5	V <sub>DDD</sub> + 0.5	V
ΔV <sub>SS</sub>	voltage difference between V <sub>SSAn</sub> and V <sub>SSDn</sub>		-	100	mV
T <sub>stg</sub>	storage temperature		-65	+150	°C
T <sub>amb</sub>	operating ambient temperature		0	70	°C
T <sub>amb(bias)</sub>	operating ambient temperature under bias		-10	+80	°C
V <sub>esd</sub>	electrostatic discharge all pins	note 3	-2000	+2000	V

**Notes**

1. Maximum: 4.6 V.
2. Except pin XTALI.
3. Human body model: equivalent to discharging a 100 pF capacitor through a 1.5 kΩ resistor.

**12 THERMAL CHARACTERISTICS**

SYMBOL	PARAMETER	CONDITIONS	VALUE	UNIT
R <sub>th(j-a)</sub>	thermal resistance from junction to ambient	in free air	54	K/W

**PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler**

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler

SAA7114H

SYMBOL	PARAMETER	CONDITIONS	MIN.	TYP.	MAX.	UNIT
$t_f$	fall time	2.6 to 0.6 V	–	–	5	ns
<b>Data and control signal output timing I-port, related to ICLK output (for IPCK[1:0]87H[5:4] = 00 is default)</b>						
$C_L$	output load capacitance at all outputs		15	–	50	pF
$t_{\text{OHD;DAT}}$	output data hold time	$C_L = 15 \text{ pF}$	–	12	–	ns
$t_{\text{o(d)}}$	output delay time	$C_L = 15 \text{ pF}$	–	22	–	ns
$t_{\text{dis}}$	port disable time to 3-state	$C_L = 25 \text{ pF}$	–	–	<tbf>	ns
$t_{\text{en}}$	port enable time from 3-state	$C_L = 25 \text{ pF}$	–	–	<tbf>	ns
<b>ICLK input timing</b>						
$T_{\text{cy}}$	cycle time		31	–	100	ns
$t_L, t_H$	LOW and HIGH times		–	–	<tbf>	ns
$t_r$	rise time		–	–	<tbf>	ns
<b>Data and control signal output timing I-port, related to ICLK input (for ICKS[1:0]80H[1:0] = 11)</b>						
$C_L$	output load capacitance at all outputs		<tbf>	–	<tbf>	pF
$t_{\text{OHD;DAT}}$	output data hold time	$C_L = 15 \text{ pF}$	–	<tbf>	–	ns
$t_{\text{o(d)}}$	output delay time	$C_L = 15 \text{ pF}$	–	<tbf>	–	ns
$t_{\text{dis}}$	port disable time to 3-state	$C_L = 25 \text{ pF}$	–	–	<tbf>	ns
$t_{\text{en}}$	port enable time from 3-state	$C_L = 25 \text{ pF}$	–	–	<tbf>	ns

**Notes**

1. The levels must be measured with load circuits; 1.2 k $\Omega$  at 3 V (TTL load);  $C_L = 50 \text{ pF}$ .
2. The effects of rise and fall times are included in the calculation of  $t_{\text{OHD;DAT}}$  and  $t_{\text{PD}}$ . Timings and levels refer to drawings and conditions illustrated in Fig.39.
3. The crystal oscillator drive level is typical 0.28 mW.

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

15 I<sup>2</sup>C-BUS DESCRIPTION

The SAA7114H supports the 'fast mode' I<sup>2</sup>C-bus specification extension (data rate up to 400 kbits/s).

15.1 I<sup>2</sup>C-bus format

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler

SAA7114H

**Table 34** Description of I<sup>2</sup>C-bus format

CODE	DESCRIPTION
S	START condition
Sr	repeated START condition
Slave address W	'0100 0010' (= 42H, default) or '0100 0000' (= 40H; note 1)
Slave address R	'0100 0011' (= 43H, default) or '0100 0001' (= 41H; note 1)
ACK-s	acknowledge generated by the slave
ACK-m	acknowledge generated by the master
Subaddress	subaddress byte; see Tables 35 and 36
Data	data byte; see Table 36; if more than one byte DATA is transmitted the subaddress pointer is automatically incremented
P	STOP condition
X	read/write control bit (LSB slave address); X = 0, order to write (the circuit is slave receiver); X = 1, order to read (the circuit is slave transmitter)

**Note**

1. If pin RTCO strapped to ground via a 3.3 kΩ resistor.

SAA7114H

## 15.2.19 SUBADDRESS 12H

**Table 55** RT signal control: RTS0 output; 12H[3:0]

The polarity of any signal on RTS0 can be inverted via RTP0[11H[3]].

RTS0 OUTPUT	RTSE03	RTSE02	RTSE01	RTSE00
3-state	0	0	0	0
Constant LOW	0	0	0	1
CREF (13.5 MHz toggling pulse; see Fig.23)	0	0	1	0
CREF2 (6.75 MHz toggling pulse; see Fig.23)	0	0	1	1
HL; horizontal lock indicator (note 1): HL = 0: unlocked HL = 1: locked	0	1	0	0
VL; vertical and horizontal lock: VL = 0: unlocked VL = 1: locked	0	1	0	1
DL, vertical and horizontal lock and colour detected: DL = 0: unlocked DL = 1: locked	0	1	1	0
Reserved	0	1	1	1
HREF, horizontal reference signal; indicates 720 pixels valid data on the expansion port. The positive slope marks the beginning of a new active line. HREF is also generated during the vertical blanking interval (see Fig.23).	1	0	0	0
HS: programmable width in LLC8 steps via HSB[7:0]06H[7:0] and HSS[7:0]07H[7:0] fine position adjustment in LLC2 steps via HDEL[1:0]11H[5:4] (see Fig.23)	1	0	0	1
HQ; HREF gated with VGATE	1	0	1	0
Reserved	1	0	1	1
V123; vertical sync (see vertical timing diagrams Figs 21 and 22)	1	1	0	0
VGATE; programmable via VSTA[8:0]17H[0]15H[7:0], VSTO[8:0]17H[1]16H[7:0] and VGPS[17H[2]]	1	1	0	1
LSBs of the 9-bit ADC's	1	1	1	0
FID; position programmable via STA[8:0]17H[0]15H[7:0]; see vertical timing diagrams Figs 21 and 22	1	1	1	1

### Note

- Function of HL is selectable via HLSEL[13H[3]]:
  - HLSEL = 0: HL is standard horizontal lock indicator.
  - HLSEL = 1: HL is fast horizontal lock indicator (use is not recommended for sources with unstable timebase e.g. VCRs).

**PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler**

**SAA7114H**

**Table 56** RT signal control: RTS1 output; 12H[7:4]

The polarity of any signal on RTS1 can be inverted via RTP1[11H[6]].

<b>RTS1 OUTPUT</b>	<b>RTSE13</b>	<b>RTSE12</b>	<b>RTSE11</b>	<b>RTSE10</b>
3-state	0	0	0	0
Constant LOW	0	0	0	1
CREF (13.5 MHz toggling pulse; see Fig.23)	0	0	1	0
CREF2 (6.75 MHz toggling pulse; see Fig.23)	0	0	1	1
HL; horizontal lock indicator (note 1): HL = 0: unlocked HL = 1: locked	0	1	0	0
VL; vertical and horizontal lock: VL = 0: unlocked VL = 1: locked	0	1	0	1
DL, vertical and horizontal lock and colour detected: DL = 0: unlocked DL = 1: locked	0	1	1	0
Reserved	0	1	1	1
HREF, horizontal reference signal; indicates 720 pixels valid data on the expansion port. The positive slope marks the beginning of a new active line. HREF is also generated during the vertical blanking interval (see Fig.23).	1	0	0	0
HS: programmable width in LLC8 steps via HSB[7:0]06H[7:0] and HSS[7:0]07H[7:0] fine position adjustment in LLC2 steps via HDEL[1:0]11H[5:4] (see Fig.23)	1	0	0	1
HQ; HREF gated with VGATE	1	0	1	0
Reserved	1	0	1	1
V123; vertical sync (see vertical timing diagrams Figs 21 and 22)	1	1	0	0
VGATE; programmable via VSTA[8:0]17H[0]15H[7:0], VSTO[8:0]17H[1]16H[7:0] and VGPS[17H[2]]	1	1	0	1
LSBs of the 9-bit ADC's	1	1	1	0
FID; position programmable via STA[8:0]17H[0]15H[7:0]; see vertical timing diagrams Figs 21 and 22	1	1	1	1

**Note**

1. Function of HL is selectable via HLSEL[13H[3]]:
  - a) HLSEL = 0: HL is standard horizontal lock indicator.
  - b) HLSEL = 1: HL is fast horizontal lock indicator (use is not recommended for sources with unstable timebase e.g. VCRs).

## 15.4.2 SUBADDRESSES 41H TO 57H

**Table 71** Line control register; LCR2 to LCR24 (41H to 57H)

See Sections 8.2 and 8.4.

NAME	DESCRIPTION	FRAMING CODE	D[7:4] (41H TO 57H)	D[3:0] (41H TO 57H)
			DT[3:0]62H[3:0] (FIELD 1)	DT[3:0]62H[3:0] (FIELD 2)
WST625	teletext EuroWST, CCST	27H	0000	0000
CC625	European closed caption	001	0001	0001
VPS	video programming service	9951H	0010	0010
WSS	wide screen signalling bits	1E3C1FH	0011	0011
WST525	US teletext (WST)	27H	0100	0100
CC525	US closed caption (line 21)	001	0101	0101
Test line	video component signal, VBI region	–	0110	0110
Intercast	raw data	–	0111	0111
General text	teletext	programmable	1000	1000
VITC625	VITC/EBU time codes (Europe)	programmable	1001	1001
	VITC/SMPTE time codes (USA)	programmable	1010	1010
Reserved	reserved	–	1011	1011
NABTS	US NABTS	–	1100	1100
Japtext	MOJI (Japanese)	programmable (A7H)	1101	1101
JFS	Japanese format switch (L20/22)	programmable	1110	1110
Active video	<b>video component signal, active video region (default)</b>	–	1111	1111

## 15.4.3 SUBADDRESS 58H

**Table 72** Programmable framing code; slicer set 58H[7:0]

According to Tables 14 and 71.

FRAMING CODE FOR PROGRAMMABLE DATA TYPES	CONTROL BITS D7 TO D0
Default value	FC[7:0] = 40H

## 15.4.4 SUBADDRESS 59H

**Table 73** Horizontal offset for slicer; slicer set 59H and 5BH

HORIZONTAL OFFSET	CONTROL BITS D[2:0]5BH[2:0]	CONTROL BITS D[7:0]59H[7:0]
Recommended value	HOFF[10:8] = 3H	HOFF[7:0] = 47H

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler

SAA7114H

## 15.4.5 SUBADDRESS 5AH

**Table 74** Vertical offset for slicer; slicer set 5AH and 5BH

VERTICAL OFFSET	CONTROL BIT D[4]5BH[4]	CONTROL BITS D[7:0]5AH[7:0]
	VOFF8	VOFF[7:0]
Minimum value 0	0	00H
Maximum value 312	1	38H
Value for 50 Hz 625 lines input	0	03H
Value for 60 Hz 525 lines input	0	06H

## 15.4.6 SUBADDRESS 5BH

**Table 75** Field offset, and MSBs for horizontal and vertical offsets; slicer set 5BH[7:6]

See Sections 15.4.4 and 15.4.5 for HOFF[10:8]5BH[2:0] and VOFF8[5BH[4]].

BIT	DESCRIPTION	SYMBOL	VALUE	FUNCTION
D7	field offset	FOFF	0	no modification of internal field indicator (default for 50 Hz 625 lines input sources)
			1	invert field indicator (default for 60 Hz 525 lines input sources)
D6	recode	RECODE	0	<b>let data unchanged (default)</b>
			1	convert 00H and FFH data bytes into 03H and FCH

## 15.4.7 SUBADDRESS 5DH

**Table 76** Header and data identification (DID; ITU 656) code control; slicer set 5DH[7:0]

BIT	DESCRIPTION	SYMBOL	VALUE	FUNCTION
D7	field ID and V-blank selection for text output (F and V reference selection)	FVREF	0	F and V output of slicer is LCR table dependent
			1	F and V output is taken from decoder real time signals EVEN_CCIR and VBLNK_CCIR
D[5:0]	<b>default; DID[5:0] = 00H</b>	DID[5:0]	00 0000	<b>ANC header framing</b> ; see Fig.30 and Table 20
	special cases of DID programming		11 1110	DID[5:0] = 3EH SAV/EAV framing, with FVREF = 1
			11 1111	DID[5:0] = 3FH SAV/EAV framing, with FVREF = 0

## 15.4.8 SUBADDRESS 5EH

**Table 77** Sliced data identification (SDID) code; slicer set 5EH[5:0]

BIT	DESCRIPTION	SYMBOL	VALUE	FUNCTION
D[5:0]	SDID codes	SDID[5:0]	00H	<b>default</b>

# PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

## 15.4.9 SUBADDRESS 60H (READ-ONLY REGISTER)

**Table 78** Slicer status byte 0; 60H[6:2]

BIT	DESCRIPTION	SYMBOL	VALUE	FUNCTION
D6	framing code valid	FC8V	0	no framing code (0 error) in the last frame detected
			1	framing code with 0 error detected
D5	framing code valid	FC7V	0	no framing code (1 error) in the last frame detected
			1	framing code with 1 error detected
D4	VPS valid	VPSV	0	no VPS in the last frame
			1	VPS detected
D3	PALplus valid	PPV	0	no PALplus in the last frame
			1	PALplus detected
D2	close caption valid	CCV	0	no closed caption in the last frame
			1	closed caption detected

## 15.4.10 SUBADDRESSES 61H AND 62H (READ-ONLY REGISTERS)

**Table 79** Slicer status byte 1; 61H[5:0] and slicer status byte 2; 62H[7:0]

SUBADDRESS	BIT	SYMBOL	DESCRIPTION
61H	D5	F21_N	field ID as seen by the VBI slicer; for field 1: D5 = 0
	D[4:0]	LN[8:4]	line number
62H	D[7:4]	LN[3:0]	
	D[3:0]	DT[3:0]	data type; according to Table 14

## 15.5 Programming register interfaces and scaler part

### 15.5.1 SUBADDRESS 80H

**Table 80** Global control 1; global set 80H[3:0]

X = don't care.

I-PORT AND SCALER BACK-END CLOCK SELECTION	CONTROL BITS D3 TO D0			
	ICKS3	ICKS2	ICKS1	ICKS0
ICLK output and back-end clock is line-locked clock LLC from decoder	X	X	0	0
ICLK output and back-end clock is XCLK from X-port	X	X	0	1
ICLK output is LLC and back-end clock is LLC2 clock	X	X <sup>(1)</sup>	1	0
Back-end clock is the ICLK input	X	X	1	1
IDQ pin carries the data qualifier	X	0	X	X
IDQ pin carries a gated back-end clock (IDQ AND CLK)	X	1	X	X
IDQ generation only for valid data	0	X	X	X
IDQ qualifies valid data inside the scaling region and all data outside the scaling region	1	X	X	X

### Note

1. Although the ICLKO I/O is independent of ICKS2 and ICKS3, this selection can only be used if ICKS2 = 1.

# PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

**Table 81** Global control 1; global set 80H[6:4]

SWRST moved to subaddress 88H[5]; X = don't care.

TASK ENABLE CONTROL	CONTROL BITS D6 TO D4		
	SMOD	TEB	TEA
Task of register set A is disabled	X	X	0
Task of register set A is enabled	X	X	1
Task of register set B is disabled	X	0	X
Task of register set B is enabled	X	1	X
The scaler window defines the F and V timing of the scaler output	0	X	X
VBI-data slicer defines the F and V timing of the scaler output	1	X	X

## 15.5.2 SUBADDRESSES 83H TO 87H

**Table 82** X-port I/O enable and output clock phase control; global set 83H[5:4]

OUTPUT CLOCK PHASE CONTROL	CONTROL BITS D5 AND D4	
	XPCCK1	XPCCK0
<b>XCLK default output phase, recommended value</b>	0	0
XCLK output inverted	0	1
XCLK phase shifted by about 3 ns	1	0
XCLK output inverted and shifted by about 3 ns	1	1

**Table 83** X-port I/O enable and output clock phase control; global set 83H[2:0]

X = don't care.

X-PORT I/O ENABLE	CONTROL BITS D2 TO D0		
	XRQT	XPE1	XPE0
X-port output is disabled by software	X	0	0
X-port output is enabled by software	X	0	1
X-port output is enabled by pin XTRI at logic 0	X	1	0
X-port output is enabled by pin XTRI at logic 1	X	1	1
XRDY output signal is A/B task flag from event handler (A = 1)	0	X	X
XRDY output signal is ready signal from scaler path (XRDY = 1 means SAA7114H is ready to receive data)	1	X	X

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler

SAA7114H

**Table 84** I-port output signal definitions; global set 84H[3:0]

X = don't care.

I-PORT OUTPUT SIGNAL DEFINITIONS	CONTROL BITS D3 TO D0			
	IDV1	IDV0	IDH1	IDH0
IGPH is a H-gate signal, framing the scaler output	X	X	0	0
IGPH is an extended H-gate (framing H-gate during scaler output and scaler input H-reference outside the scaler window)	X	X	0	1
IGPH is a horizontal trigger pulse, on active going edge of H-gate	X	X	1	0
IGPH is a horizontal trigger pulse, on active going edge of extended H-gate	X	X	1	1
IGPV is a V-gate signal, framing scaled output lines	0	0	X	X
IGPV is the reference signal from scaler input	0	1	X	X
IGPV is a vertical trigger pulse, derived from V-gate	1	0	X	X
IGPV is a vertical trigger pulse derived from input V-reference	1	1	X	X

**Table 85** I-port signal definitions; global set 84H[5:4] and 86H[4]

I-PORT SIGNAL DEFINITIONS	CONTROL BITS		
	86H[4]	84H[5:4]	
	IDG12	IDG11	IDG10
IGP1 is output field ID, as defined by OFIDC[90H[6]]	0	0	0
IGP1 is A/B task flag, as defined by CONLH[90H[7]]	0	0	1
IGP1 is sliced data flag, framing the sliced VBI-data at the I-port	0	1	0
<b>IGP1 is set to logic 0 (default polarity)</b>	0	1	1
IGP1 is the output FIFO almost filled flag	1	0	0
IGP1 is the output FIFO overflow flag	1	0	1
IGP1 is the output FIFO almost full flag, level to be programmed in subaddress 86H	1	1	0
IGP1 is the output FIFO almost empty flag, level to be programmed in subaddress 86H	1	1	1

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler

SAA7114H

**Table 86** I-port signal definitions; global set 84H[7:6] and 86H[5]

I-PORT SIGNAL DEFINITIONS	CONTROL BITS		
	86H[5]	84H[7:6]	
	IDG02	IDG01	IDG00
IGP0 is output field ID, as defined by OFIDC[90H[6]]	0	0	0
IGP0 is A/B task flag, as defined by CONLH[90H[7]]	0	0	1
IGP0 is sliced data flag, framing the sliced VBI-data at the I-port	0	1	0
<b>IGP0 is set to logic 0 (default polarity)</b>	0	1	1
IGP0 is the output FIFO almost filled flag	1	0	0
IGP0 is the output FIFO overflow flag	1	0	1
IGP0 is the output FIFO almost full flag, level to be programmed in subaddress 86H	1	1	0
IGP0 is the output FIFO almost empty flag, level to be programmed in subaddress 86H	1	1	1

**Table 87** I-port reference signal polarities; global set 85H[4:0]

X = don't care.

I-PORT REFERENCE SIGNAL POLARITIES	CONTROL BITS D4 TO D0				
	IGP0P	IGP1P	IGVP	IGHP	IDQP
IDQ at default polarity (1 = active)	X	X	X	X	0
IDQ is inverted	X	X	X	X	1
IGPH at default polarity (1 = active)	X	X	X	0	X
IGPH is inverted	X	X	X	1	X
IGPV at default polarity (1 = active)	X	X	0	X	X
IGPV is inverted	X	X	1	X	X
IGP1 at default polarity	X	0	X	X	X
IGP1 is inverted	X	1	X	X	X
IGP0 at default polarity	0	X	X	X	X
IGP0 is inverted	1	X	X	X	X

**Table 88** X-port signal definitions text slicer; global set 85H[7:5]

X = don't care.

X-PORT SIGNAL DEFINITIONS TEXT SLICER	CONTROL BITS D7 TO D5		
	ISWP1	ISWP0	ILLV
Video data limited to range 1 to 254	X	X	0
Video data limited to range 8 to 247	X	X	1
Dword byte swap, influences serial output timing D0 D1 D2 D3 ⇒ FF 00 00 SAV C <sub>B0</sub> Y0 C <sub>R0</sub> Y1	0	0	X
D1 D0 D3 D2 ⇒ 00 FF SAV 00 Y0 C <sub>B0</sub> Y1 C <sub>R0</sub>	0	1	X
D2 D3 D0 D1 ⇒ 00 SAV FF 00 C <sub>R0</sub> Y1 C <sub>B0</sub> Y0	1	0	X
D3 D2 D1 D0 ⇒ SAV 00 00 FF Y1 C <sub>R0</sub> Y0 C <sub>B0</sub>	1	1	X

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler

SAA7114H

**Table 89** I-port FIFO flag control and arbitration; global set 86H[3:0]

X = don't care.

I-PORT FIFO FLAG CONTROL AND ARBITRATION	CONTROL BITS D3 TO D0			
	FFL1	FFL0	FEL1	FEL0
FAE FIFO flag almost empty level				
<16 Dwords	X	X	0	0
<8 Dwords	X	X	0	1
<4 Dwords	X	X	1	0
0 Dwords	X	X	1	1
FAF FIFO flag almost full level				
≥16 Dwords	0	0	X	X
≥24 Dwords	0	1	X	X
≥28 Dwords	1	0	X	X
32 Dwords	1	1	X	X

**Table 90** I-port FIFO flag control and arbitration; global set 86H[7:4]

X = don't care.

FUNCTION	CONTROL BITS D7 TO D4			
	VITX1	VITX0	IDG02	IDG12
See subaddress 84H: IDG11 and IDG10	X	X	X	0
	X	X	X	1
See subaddress 84H: IDG01 and IDG00	X	X	0	X
	X	X	1	X
<b>I-port signal definitions</b>				
I-port data output inhibited	0	0	X	X
Only video data are transferred	0	1	X	X
Only text data are transferred (no EAV, SAV will occur)	1	0	X	X
Text and video data are transferred, text has priority	1	1	X	X

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler

SAA7114H

**Table 91** I-port I/O enable, output clock and gated clock phase control; global set 87H[7:4]

OUTPUT CLOCK AND GATED CLOCK PHASE CONTROL	CONTROL BITS D7 TO D4 <sup>(1)</sup>			
	IPCK3 <sup>(2)</sup>	IPCK2 <sup>(2)</sup>	IPCK1	IPCK0
ICLK default output phase	X	X	0	0
ICLK phase shifted by $\frac{1}{2}$ clock cycle $\Rightarrow$ recommended for ICKS1 = 1 and ICKS0 = 0 (subaddress 80H)	X	X	0	1
ICLK phase shifted by about 3 ns	X	X	1	0
ICLK phase shifted by $\frac{1}{2}$ clock cycle + about 3 ns $\Rightarrow$ alternatively to setting '01'	X	X	1	1
IDQ = gated clock default output phase	0	0	X	X
IDQ = gated clock phase shifted by $\frac{1}{2}$ clock cycle $\Rightarrow$ recommended for gated clock output	0	1	X	X
IDQ = gated clock phase shifted by about 3 ns	1	0	X	X
IDQ = gated clock phase shifted by $\frac{1}{2}$ clock cycle + about 3 ns $\Rightarrow$ alternatively to setting '01'	1	1	X	X

**Notes**

1. X = don't care.
2. IPCK3 and IPCK2 only affects the gated clock (subaddress 80H, bit ICKS2 = 1).

**Table 92** I-port I/O enable, output clock and gated clock phase control; global set 87H[1:0]

I-PORT I/O ENABLE	CONTROL BITS D1 AND D0	
	IPE1	IPE0
I-port output is disabled by software	0	0
I-port output is enabled by software	0	1
I-port output is enabled by pin ITRI at logic 0	1	0
I-port output is enabled by pin ITRI at logic 1	1	1

## 15.5.3 SUBADDRESS 88H

**Table 93** Power save control; global set 88H[3] and 88H[1:0]

X = don't care.

POWER SAVE CONTROL	CONTROL BITS		
	88H[3]	88H[1:0]	
	SLM3	SLM1	SLM0
Decoder and VBI slicer are in operational mode	X	X	0
Decoder and VBI slicer are in power-down mode; scaler only operates, if scaler input and ICLK source is the X-port (refer to subaddresses 80H and 91H/C1H)	X	X	1
Scaler is in operational mode	X	0	X
Scaler is in power-down mode; scaler in power-down stops I-port output	X	1	X
Audio clock generation active	0	X	X
Audio clock generation in power-down and output disabled	1	X	X

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler

SAA7114H

**Table 94** Power save control; global set 88H[7:4]

POWER SAVE CONTROL	CONTROL BITS D7 TO D4 <sup>(1)</sup>			
	CH4EN	CH2EN	SWRST <sup>(2)</sup>	DPROG
DPROG = 0 after reset	X	X	X	0
DPROG = 1 can be used to assign that the device has been programmed; this bit can be monitored in the scalers status byte, bit PRDON; if DPROG was set to logic 1 and PRDON status bit shows a logic 0 a power- or start-up fail has occurred	X	X	X	1
Scaler path is reset to it's idle state, software reset	X	X	0	X
Scaler is switched back to operation	X	X	1	X
AD1x analog channel is in power-down mode	X	0	X	X
AD1x analog channel is active	X	1	X	X
AD2x analog channel is in power-down mode	0	X	X	X
AD2x analog channel is active	1	X	X	X

**Notes**

1. X = don't care.
2. Bit SWRST is now located here.

## 15.5.4 SUBADDRESS 8FH (READ-ONLY REGISTER)

**Table 95** Status information scaler part; 8FH[7:0]

BIT	I2C-BUS STATUS BIT	FUNCTION <sup>(1)</sup>
D7	XTRI	status on input pin XTRI, if not used for 3-state control, usable as hardware flag for software use
D6	ITRI	status on input pin ITRI, if not used for 3-state control, usable as hardware flag for software use
D5	FFIL	status of the internal 'FIFO almost filled' flag
D4	FFOV	status of the internal 'FIFO overflow' flag
D3	PRDON	copy of bit DPROG, can be used to detect power-up and start-up fails
D2	ERR_OF	error flag of scalers output formatter, normally set, if the output processing needs to be interrupted, due to input/output data rate conflicts, e.g. if output data rate is much too low and all internal FIFO capacity used
D1	FIDSCI	status of the field sequence ID at the scalers input
D0	FIDSCO	status of the field sequence ID at the scalers output, scaler processing dependent

**Note**

1. Status information is unsynchronized and shows the actual status at the time of I<sup>2</sup>C-bus read.

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler

SAA7114H

## 15.5.5 SUBADDRESSES 90H AND C0H

**Table 96** Task handling control; register set A (90H[2:0]) and B (C0H[2:0])

X = don't care.

EVENT HANDLER CONTROL	CONTROL BITS D2 TO D0		
	RPTSK	STRC1	STRC0
Event handler triggers immediately after finishing a task	X	0	0
Event handler triggers with next V-sync	X	0	1
Event handler triggers with field ID = 0	X	1	0
Event handler triggers with field ID = 1	X	1	1
If active task is finished, handling is taken over by the next task	0	X	X
Active task is repeated once, before handling is taken over by the next task	1	X	X

**Table 97** Task handling control; register set A (90H[5:3]) and B (C0H[5:3])

EVENT HANDLER CONTROL	CONTROL BITS D5 TO D3		
	FSKP2	FSKP1	FSKP0
Active task is carried out directly	0	0	0
1 field is skipped before active task is carried out	0	0	1
... fields are skipped before active task is carried out	...	...	...
6 fields are skipped before active task is carried out	1	1	0
7 fields are skipped before active task is carried out	1	1	1

**Table 98** Task handling control; register set A (90H[7:6]) and B (C0H[7:6])

X = don't care.

EVENT HANDLER CONTROL	CONTROL BITS D7 AND D6	
	CONLH	OFIDC
Output field ID is field ID from scaler input	X	0
Output field ID is task status flag, which changes every time an selected task is activated (not synchronized to input field ID)	X	1
<b>Scaler SAV/EAV byte bit D7 and task flag = 1, default</b>	0	X
Scaler SAV/EAV byte bit D7 and task flag = 0	1	X

# PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

## 15.5.6 SUBADDRESSES 91H TO 93H

**Table 99** X-port formats and configuration; register set A (91H[2:0]) and B (C1H[2:0])

SCALER INPUT FORMAT AND CONFIGURATION FORMAT CONTROL	CONTROL BITS D2 TO D0 <sup>(1)</sup>		
	FSC2 <sup>(2)</sup>	FSC1 <sup>(2)</sup>	FSC0
Input is YUV 4 : 2 : 2 like sampling scheme	X	X	0
Input is YUV 4 : 1 : 1 like sampling scheme	X	X	1
<b>Chroma is provided every line, default</b>	0	0	X
Chroma is provided every 2nd line	0	1	X
Chroma is provided every 3rd line	1	0	X
Chroma is provided every 4th line	1	1	X

### Notes

1. X = don't care.
2. FSC2 and FSC1 only to be used, if X-port input source don't provide chroma information for every input line. X-port input stream must contain dummy chroma bytes.

**Table 100** X-port formats and configuration; register set A (91H[7:3]) and B (C1H[7:3])

X = don't care.

SCALER INPUT FORMAT AND CONFIGURATION SOURCE SELECTION	CONTROL BITS D7 TO D3				
	CONLV	HLDFV	SCSRC1	SCSRC0	SCRQE
Only if XRQT[83H[2]] = 1: scaler input source reacts on SAA7114H request	X	X	X	X	0
Scaler input source is a continuous data stream, which cannot be interrupted (must be logic 1, if SAA7114H decoder part is source of scaler or XRQT[83H[2]] = 0)	X	X	X	X	1
Scaler input source is data from decoder, data type is provided according to Table 14	X	X	0	0	X
Scaler input source is YUV data from X-port	X	X	0	1	X
Scaler input source is raw digital CVBS from selected analog channel, for backward compatibility only, further use is not recommended	X	X	1	0	X
Scaler input source is raw digital CVBS (or 16-bit Y + UV, if no 16-bit output are active) from X-port	X	X	1	1	X
SAV/EAV code bits D6 and D5 (F and V) may change between SAV and EAV	X	0	X	X	X
SAV/EAV code bits D6 and D5 (F and V) are synchronized to scalers output line start	X	1	X	X	X
SAV/EAV code bit D5 (V) and V-gate on pin IGPV as generated by the internal processing, see Fig.36	0	X	X	X	X
SAV/EAV code bit D5 (V) and V-gate are inverted	1	X	X	X	X

**PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler**

SAA7114H

**Table 101** X-port input reference signal definitions; register set A (92H[3:0]) and B (C2H[3:0])

X = don't care.

X-PORT INPUT REFERENCE SIGNAL DEFINITIONS	CONTROL BITS D3 TO D0			
	XCODE	XDH	XDQ	XCKS
XCLK input clock and XDQ input qualifier are needed	X	X	X	0
Data rate is defined by XCLK only, no XDQ signal used	X	X	X	1
Data are qualified at XDQ input at logic 1	X	X	0	X
Data are qualified at XDQ input at logic 0	X	X	1	X
Rising edge of XRH input is horizontal reference	X	0	X	X
Falling edge of XRH input is horizontal reference	X	1	X	X
Reference signals are taken from XRH and XRV	0	X	X	X
Reference signals are decoded from EAV and SAV	1	X	X	X

**Table 102** X-port input reference signal definitions; register set A (92H[7:4]) and B (C2H[7:4])

X = don't care.

SCALER INPUT REFERENCE SIGNAL DEFINITIONS	CONTROL BITS D7 TO D4			
	XFDV	XFDH	XDV1	XDV0
Rising edge of XRV input and decoder V123 is vertical reference	X	X	X	0
Falling edge of XRV input and decoder V123 is vertical reference	X	X	X	1
XRV is a V-sync or V-gate signal	X	X	0	X
XRV is a frame sync, V-pulses are generated internally on both edges of FS input	X	X	1	X
X-port field ID is state of XRH at reference edge on XRV (defined by XFDV)	X	0	X	X
Field ID (decoder and X-port field ID) is inverted	X	1	X	X
Reference edge for field detection is falling edge of XRV	0	X	X	X
Reference edge for field detection is rising edge of XRV	1	X	X	X

## 16 PROGRAMMING START SET-UP

### 16.1 Decoder part

The given values force the following behaviour of the SAA7114H decoder part:

- The analog input AI11 expects an NTSC M, PAL BDGHI or SECAM signal in CVBS format; analog anti-alias filter and AGC active
- Automatic field detection enabled
- Standard ITU 656 output format enabled on expansion (X) port
- Contrast, brightness and saturation control in accordance with ITU standards
- Adaptive comb filter for luminance and chrominance activated
- Pins LLC, LLC2, XTOUT, RTS0, RTS1 and RTCO are set to 3-state.

**Table 127** Decoder part start set-up values for the three main standards

SUB ADDRESS (HEX)	REGISTER FUNCTION	BIT NAME <sup>(1)</sup>	VALUES (HEX)

SAA7114H

## 16.2 Audio clock generation part

The given values force the following behaviour of the SAA7114H audio clock generation part:

- Used crystal is 24.576 MHz
- Expected field frequency is 59.94 Hz (e.g. NTSC M standard)
- Generated audio master clock frequency at pin AMCLK is  $256 \times 44.1 \text{ kHz} = 11.2896 \text{ MHz}$
- AMCLK is externally connected to AMXCLK (short-cut between pins 37 and 41)
- ASCLK =  $32 \times 44.1 \text{ kHz} = 1.4112 \text{ MHz}$
- ALRCLK is 44.1 kHz.

**Table 128** Audio clock part set-up values

SUB ADDRESS (HEX)	REGISTER FUNCTION	BIT NAME <sup>(1)</sup>	START VALUES								
			7	6	5	4	3	2	1	0	HEX
30	audio master clock cycles per field; bits 7 to 0	ACPF7 to ACPF0	1	0	1	1	1	1	0	0	BC

SAA7114H

## 16.3 Data slicer and data type control part

The given values force the following behaviour of the SAA7114H VBI-data slicer part:

- Closed captioning data are expected at line 21 of field 1 (60 Hz/525 line system)
- All other lines are processed as active video
- Sliced data are framed by ITU 656 like SAV/EAV sequence (DID[5:0] = 3EH  $\Rightarrow$  MSB of SAV/EAV = 1).

**Table 129** Data slicer start set-up values

# PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC comb filter, VBI-data slicer and high performance scaler

SAA7114H

## 16.4 Scaler and interfaces

Table 130 shows some examples for the scaler programming with:

- prsc = prescale ratio
- fisc = fine scale ratio
- vsc = vertical scale ratio.

The ratio is defined as:  $\frac{\text{number of input pixel}}{\text{number of output pixel}}$

In the following settings the VBI-data slicer is inactive. To activate the VBI-data slicer, VITX[1:0]86H[7:6] has to be set to '11'. Dependent on the VBI-data slicer settings, the sliced VBI-data are inserted after end of scaled video lines, if the regions of VBI-data slicer and scaler overlaps.

To compensate the running-in of the vertical scaler, the vertical input window lengths are extended by 2 to 290 lines, respectively 242 lines for XS, but the scaler increment calculations are done with 288, respectively 240 lines.

### 16.4.3 EXAMPLES

**Table 130** Example configurations

EXAMPLE NUMBER	SCALER SOURCE AND REFERENCE EVENTS	INPUT WINDOW	OUTPUT WINDOW	SCALE RATIOS
1	analog input to 8-bit I-port output, with SAV/EAV codes, 8-bit serial byte stream decoder output at X-port; acquisition trigger at falling edge vertical and rising edge horizontal reference signal; H and V-gates on IGPH and IGPV, IGP0 = VBI sliced data flag, IGP1 = FIFO almost full, level $\geq 24$ , IDQ qualifier logic 1 active	720 × 240	720 × 240	prsc = 1; fisc = 1; vsc = 1
2	analog input to 16-bit output, without SAV/EAV codes, Y on I-port, UV on H-port and decoder output at X-port; acquisition trigger at falling edge vertical and rising edge horizontal reference signal; H and V-pulses on IGPH and IGPV, output FID on IGP0, IGP1 fixed to logic 1, IDQ qualifier logic 0 active	704 × 288	768 × 288	prsc = 1; fisc = 0.91667; vsc = 1
3	X-port input 8 bit with SAV/EAV codes, no reference signals on XRH and XRV, XCLK as gated clock; field detection and acquisition trigger on different events; acquisition triggers at rising edge vertical and rising edge horizontal; I-port output 8 bit with SAV/EAV codes like example number 1	720 × 240	352 × 288	prsc = 2; fisc = 1.022; vsc = 0.8333
4	X-port and H-port for 16-bit YUV 4 : 2 : 2 input (if no 16-bit output selected); XRH and XRV as references; field detection and acquisition trigger at falling edge vertical and rising edge horizontal; I-port output 8 bit with SAV/EAV codes, but Y only output	720 × 288	200 × 80	prsc = 2; fisc = 1.8; vsc = 3.6

### 16.4.1 TRIGGER CONDITION

For trigger condition STRC[1:0]90H[1:0] not equal '00'.

If the value of (YO + YS) is greater equal 262 (NTSC), respectively 312 (PAL) the output field rate is reduced to 30 Hz, respectively 25 Hz.

Horizontal and vertical offsets (XO and YO) have to be used to adjust the displayed video in the display window. As this adjustment is application dependent, the listed values are only dummy values.

### 16.4.2 MAXIMUM ZOOM FACTOR

The maximum zoom factor is dependent on the back-end data rate and therefore back-end clock and data format dependent (8 or 16-bit output). The maximum horizontal zoom is limited to about 3.5, due to internal data path restrictions.

## 18 SOLDERING

### 18.1 Introduction to soldering surface mount packages

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our *"Data Handbook IC26; Integrated Circuit Packages"* (document order number 9398 652 90011).

There is no soldering method that is ideal for all surface mount IC packages. Wave soldering is not always suitable for surface mount ICs, or for printed-circuit boards with high population densities. In these situations reflow soldering is often used.

### 18.2 Reflow soldering

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several methods exist for reflowing; for example, infrared/convection heating in a conveyor type oven. Throughput times (preheating, soldering and cooling) vary between 100 and 200 seconds depending on heating method.

Typical reflow peak temperatures range from 215 to 250 °C. The top-surface temperature of the packages should preferably be kept below 230 °C.

### 18.3 Wave soldering

Conventional single wave soldering is not recommended for surface mount devices (SMDs) or printed-circuit boards with a high component density, as solder bridging and non-wetting can present major problems.

To overcome these problems the double-wave soldering method was specifically developed.

If wave soldering is used the following conditions must be observed for optimal results:

- Use a double-wave soldering method comprising a turbulent wave with high upward pressure followed by a smooth laminar wave.

- For packages with leads on two sides and a pitch (e):
  - larger than or equal to 1.27 mm, the footprint longitudinal axis is **preferred** to be parallel to the transport direction of the printed-circuit board;
  - smaller than 1.27 mm, the footprint longitudinal axis **must** be parallel to the transport direction of the printed-circuit board.

The footprint must incorporate solder thieves at the downstream end.

- For packages with leads on four sides, the footprint must be placed at a 45° angle to the transport direction of the printed-circuit board. The footprint must incorporate solder thieves downstream and at the side corners.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

### 18.4 Manual soldering

Fix the component by first soldering two diagonally-opposite end leads. Use a low voltage (24 V or less) soldering iron applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C.

When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.

PAL/NTSC/SECAM video decoder with adaptive PAL/NTSC  
comb filter, VBI-data slicer and high performance scaler

SAA7114H

### 18.5 Suitability of surface mount IC packages for wave and reflow soldering methods

PACKAGE	SOLDERING METHOD	
	WAVE	REFLOW <sup>(1)</sup>
BGA, SQFP	not suitable	suitable
HLQFP, HSQFP, HSOP, SMS	not suitable <sup>(2)</sup>	suitable
PLCC <sup>(3)</sup> , SO, SOJ	suitable	suitable
LQFP, QFP, TQFP	not recommended <sup>(3)(4)</sup>	suitable
SSOP, TSSOP, VSO	not recommended <sup>(5)</sup>	suitable

#### Notes

1. All surface mount (SMD) packages are moisture sensitive. Depending upon the moisture content, the maximum temperature (with respect to time) and body size of the package, there is a risk that internal or external package cracks may occur due to vaporization of the moisture in them (the so called popcorn effect). For details, refer to the Drypack information in the "Data Handbook IC26; Integrated Circuit Packages; Section: Packing Methods".
2. These packages are not suitable for wave soldering as a solder joint between the printed-circuit board and heatsink (at bottom version) can not be achieved, and as solder may stick to the heatsink (on top version).
3. If wave soldering is considered, then the package must be placed at a 45° angle to the solder wave direction. The package footprint must incorporate solder thieves downstream and at the side corners.
4. Wave soldering is only suitable for LQFP, TQFP and QFP packages with a pitch (e) equal to or larger than 0.8 mm; it is definitely not suitable for packages with a pitch (e) equal to or smaller than 0.65 mm.
5. Wave soldering is only suitable for SSOP and TSSOP packages with a pitch (e) equal to or larger than 0.65 mm; it is definitely not suitable for packages with a pitch (e) equal to or smaller than 0.5 mm.

## 19 DEFINITIONS

<b>Data sheet status</b>	
Objective specification	This data sheet contains target or goal specifications for product development.
Preliminary specification	This data sheet contains preliminary data; supplementary data may be published later.
Product specification	This data sheet contains final product specifications.
<b>Limiting values</b>	
Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.	
<b>Application information</b>	
Where application information is given, it is advisory and does not form part of the specification.	

## 20 LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.

## 21 PURCHASE OF PHILIPS I<sup>2</sup>C COMPONENTS

Purchase of Philips I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C system provided the system conforms to the I<sup>2</sup>C specification defined by Philips. This specification can be ordered using the code 9398 393 40011.
