L78LR05**150mA, 5V 5-Pin Voltage Regulator
with Reset Function****Overview**

The L78LR05 is a voltage regulator IC that performs the reset signal generating function when the power supply of a microcomputer system is turned ON/OFF. The L78LR05 is convenient for battery backup system at the time of power failure. The reset threshold voltage V_{RT} is ranked as shown below.

V_{RT} rank	B	C	D	E	F	G	H
V_{RT} (V)	4.8	4.5	4.2	3.9	3.6	3.3	3.0

Applications

- Prevention of malfunction that may occur when the power supply of a microcomputer is turned ON/OFF.
- Measures taken against abnormal operations that may occur at the time of instantaneous break of power supply
- Direct battery backup for SRAM

Features

- 5V, 150mA output
- Capable of generating a microcomputer reset signal
- No battery-regulator switching circuit required at the battery backup mode (Output leakage current: $2\mu\text{A}$ or less)
- An external capacitor can be used to set the reset output delay time.
- Applicable to the power supply of CMOS, NMOS microcomputers
- Especially suited for use as an on-board regulator for a microcomputer system
- Small-sized power package TP-5H permitting the equipment to be made compact
- The allowable power dissipation can be increased by being surface-mounted on the board.
- Capable of being mounted in a variety of methods because of various lead forming versions available
- On-chip protectors (overcurrent limiter, ASO protector, thermal protector)

Package Dimensions
(unit: mm)

3103

L78LR05

Sample Application Circuit 1

Note 1: When the capacitance of C_d is large, the capacitor may not discharge completely, causing t_d to be made shorter than a set value. If this is a problem, either connect a high speed diode (DS442) between pin2 (anode side) and pin5 (cathode side) or ensure an adequate discharge time by using values for capacitors C_{in} and C_d such that $C_{in} > C_d$.

Note 2: If a pull-up resistor is connected to the reset output pin externally, it is possible to cause a sink current up to 4mA to flow.

Reset Operation

Sample Application Circuit 2 (Direct battery backup)

Since the leakage current at the output pin (pin5) of the L78LR05 is so low as $2\mu A$ or less, a backup circuit can be implemented by connecting an electric double layer capacitor (super capacitor: NEC, gold capacitor: Matsushita Electric) or a Ni Cd battery direct to the output pin. Since a reverse blocking diode, which has been so far connected to the output pin, is not required, a regulated power-supply voltage can be supplied to a load during the steady-state operation, without voltage drop caused by the diode and effects of temperature characteristics, current characteristics of the diode. No battery-regulator switching circuit is required at the battery backup start mode.

Note 3: The capacitance of reset output signal delay capacitor C_d must exceed that of input capacitor C_{in} . If the capacitance of C_d is small, a reset pulse signal may be generated once when the main power source is turned off (at the battery backup start mode).

L78LR05

Allowable Power Dissipation

The allowable power dissipation is 1.0W ($T_a=25^\circ\text{C}$) with no fin attached. When the L78LR05 is surface-mounted on a hybrid IC board or printed circuit board, a high allowable power dissipation can be obtained, though it is placed in a small-sized package. Shown below is the relationship between the Cu-foiled area and the allowable power dissipation when the L78LR05 is surface-mounted on a glass epoxy board ($50 \times 50 \times 0.8\text{mm}^3$).

* The measured values of P_d represent the values measured when solder on the Cu-foiled area is all wet.
