#### **DESCRIPTION**

KS51840, a 4-bit single-chip CMOS microcontroller, consists of the reliable SMCS-51 CPU core with on-chip ROM and RAM. Eight input pins and 11 output pins provide the flexibility for various I/O requirements. Auto reset circuit generates reset pulse every certain period, and every halt mode termination time. The KS51840 microcontroller has been designed for use in small system control applications that require a low-power, cost-sensitive design solution. In addition, the KS51840 has been optimized for remote control transmitter.

## **FEATURES**

ROM Size
 RAM Size
 Instruction Set
 1,024 bytes
 32 nibbles
 39 instructions

■ Instruction Cycle Time 13.2 µsec at Fxx=455 kHz

● Input Ports Two 4-bit ports(24 pins)/One 4-bit port, one 2-bit ports(20 pins)

Output Ports
 One 4-bitport, Seven1-bitports(24pins)/One 4-bit port, Five1-bit ports(20pins)

Built-in Oscillator Crystal/Ceramic resonator

■ Built-in Power-on reset and auto reset circuit for generating reset pulse every 131072/Fxx(288ms at Fxx=455kHz)

Four Transmission Frequencies ---- Fxx/12 (1/4 duty), Fxx/12 (1/3 duty), Fxx/8 (1/2 duty), and

no-carrier frequency

■ Supply Voltage 1.8V-3.6V(Fosc:250kHz-3.9MHz),2.2V-3.6V(Fosc:4MHz-6MHz)

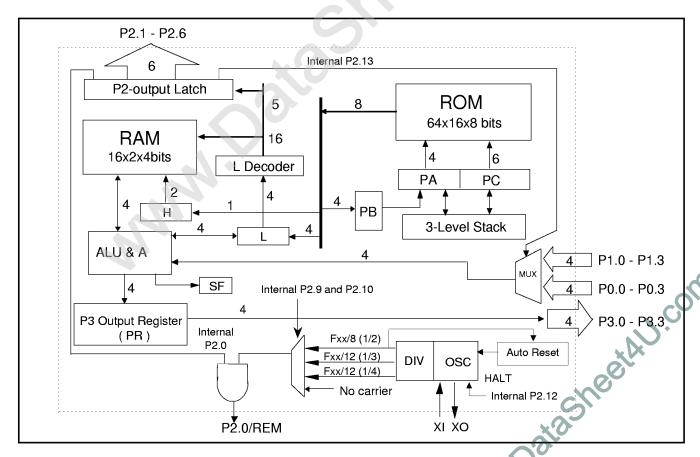

Normal mode: 0.5 mA (typical)

Operating temperature -20°C to 85°C

Package Type
 24 SOP, 20 DIP, 20 SOP

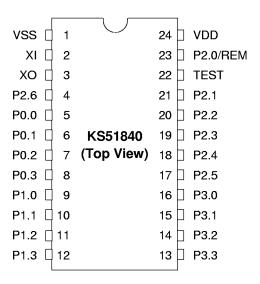

Oscillator Frequency divide select --- Mask Option= Fosc or Fosc/8

#### **BLOCK DIAGRAM**

## **PIN CONFIGURATION (24 SOP)**

#### **PIN DESCRIPTION FOR 24 PINS**

		I		T
Symbols	Pin No.	Туре	Functions	I/O Circuit Type
P0.0 - P0.3	5, 6, 7, 8	Input	4-bit input port when P2.13 is low	Α
P1.0 - P1.3	9,10,11,12	Input	4-bit input port when P2.13 is high	Α
P2.0/REM	23	Output	1-bit individual output for remote carrier frequency (1)	В
P2.2 - P2.5	20,19,18, 17	Output	1-bit individual output port	С
P2.1, P2.6	21,4			D
P3.0 - P3.3	16,15,14,13	Output	4-bit parallel output port	С
TEST	22	Input	Input pin for test (Normally connected to VSS)	
ΧI	2	Input	Oscillation clock input	_
хо	3	Output	Oscillation clock output	_
VDD	24	_	Power supply	_
Vss	1	_	Ground	_

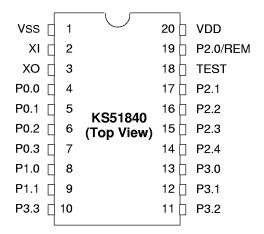

## **NOTES:**

1. The carrier can be selected by software as Fxx/12 (1/3 duty), Fxx/12 (1/4 duty), Fxx/8 (1/2 duty), or no-carrier frequency.

2. Package type can be selected as 24 SOP in the ordering sheet.

## PIN CONFIGURATION (20 DIP, 20 SOP)

#### **PIN DESCRIPTION FOR 20 PINS**

#### **FUNCTIONAL DESCRIPTION**

## **Program Memory (ROM)**

The KS51840's program memory consists of a 1024-byte ROM, organized in 16 pages. Each page is 64 bytes long. (See Figure 1–3).

ROM addressing is supported by a 10-bit register made up of two sub-registers: a 4-bit Page Address register (PA), and a 6-bit Program Counter (PC).

Pages 0 through 15 (FH) can each access 64 (3FH) bytes.

ROM addressing occurs as follows: The 10-bit register selects one of the ROM's 1024-bytes. A new address is then loaded into the PC register during each instruction cycle.

Unless a transfer-of- control instruction such as JP, CALL, or RET is encountered, the PC is loaded with the next sequential 6-bit address in the page, PC + 1. In this case, the next address of 3FH would be 00H.

Only the PAGE instruction can change the Page Buffer (PB) to a specified value.

When a JP or CALL instruction is executed, and if the Status Flag is set to "1", the contents of the PB are loaded into the PA register. If the Status Flag is "0", however, the JP or CALL is executed like NOP instruction in an instruction cycle and the Status Flag is set to "1". After that, program execution proceeds.

## Page-In Addressing

All instructions, including JP and CALL, can be executed by page. (See Figure 1–1). When the Status Flag is "1", a JP or CALL causes a program to branch to its address (operand) in a page.

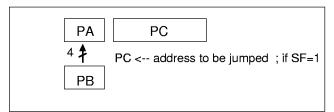

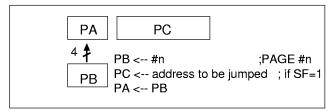

Figure 1-1. Page-In Addressing

## ● Page-To-Page Addressing

When a PAGE instruction occurs, and if the Status Flag is "1", a JP or CALL instruction will cause a program to branch to its address (operand) across the page (see Figure 1–2).

**NOTE:** If SF = 0 then PC < -- PC + 1.

Figure 1–2. Page-To-Page Addressing

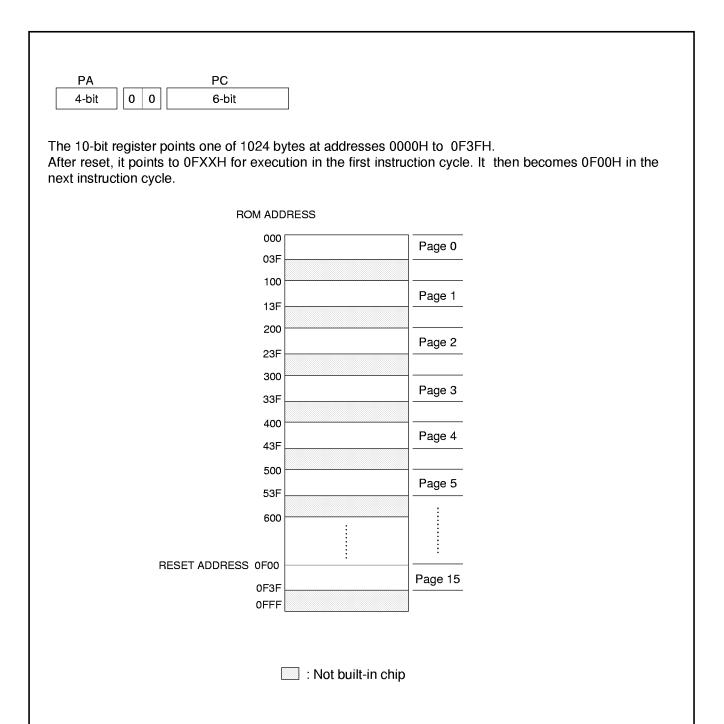

Figure 1-3. KS51840 Program Memory Map

## **DATA MEMORY (RAM)**

The KS51840's data memory consists of a 32-nibble RAM which is organized into two files of 16 nibbles each (see Figure 1–4).

RAM addressing is implemented by a 7-bit register, HL.

Its upper 3-bit register (H) selects one of two files and its lower 4-bit register (L) selects one of 16 nibbles in the selected file.

Instructions which manipulate the H and L registers are as follow :

#### Select a file:

MOV H,#n ; H <-- #n, where n must be 0,4</li>
 NOT H ; Complement MSB of H register

## Select a nibble in a selected file:

MOV L,A ; L <-- A</li>MOV L,@HL ; L <-- M(H,L)</li>

MOV L,#n ; L <-- #n, where 0 ≤ n ≤0FH</li>

INCS L ; L <-- L+1</li>DECS L ; L <-- L-1</li>

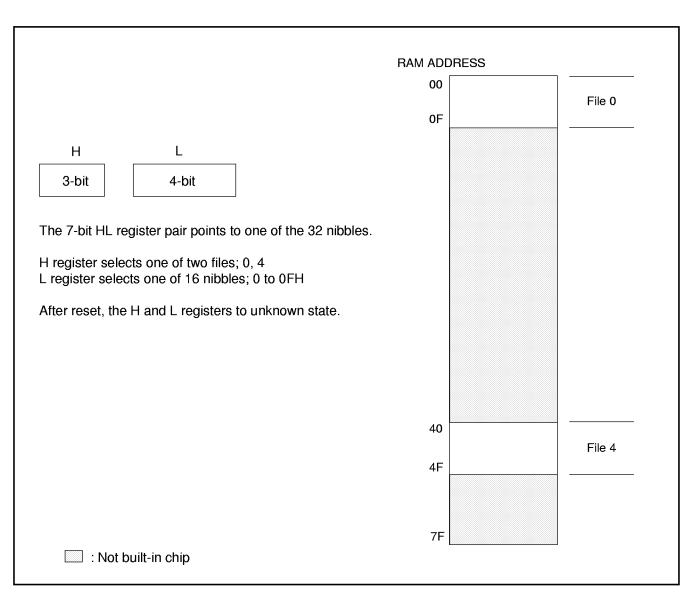

Figure 1-4. KS51840 Data Memory Map

#### **REGISTER DESCRIPTIONS**

#### Stack Register (SR)

Three levels of subroutine nesting are supported by a three-level stack as shown in Figure 1–5.

Each subroutine call (CALL) pushes the next PA and PC address into the stack. The latest stack to be stored will be overwritten and lost. Each return instruction (RET) pops the stack back into the PA and PC registers.

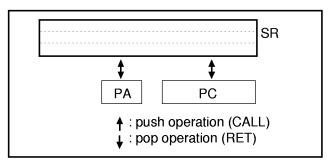

Figure 1-5. Stack Operations

## Page Address Register(PA), Page Buffer Register(PB)

The Page Address Register (PA) and Page Buffer Register (PB) are 4-bit registers. The PA always specifies the current page.

A page select instruction (PAGE #n) loads the value "n" into the PB. When JP or CALL instruction is executed, and if the Status Flag (SF) is set to 1, the contents of PB are loaded into PA. If SF is "0", however, the JP or CALL is executed like NOP instruction and SF is set to "1". The contents of PB don't be loaded. Figure 1–6 illustrates this concept.

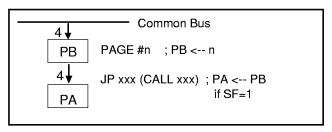

Figure 1–6. PA, PB Operations

## Arithmetic Logic Unit (ALU), Accumulator (A)

The SMCS-51 CPU contains an ALU and its own 4-bit register (accumulator) which is the source and destination register for most I/O, arithmetic, logic, and data memory access operations.

Arithmetic functions and logical operations will set the status flag (SF) to "0" or "1".

#### Status Latch (SL)

The Status Latch (SL) flag is an 1-bit flip-flop register. Only the "CPNE L,A" instruction can change the value of SL.

If the result of a "CPNE L,A" instruction is true, the SL is set to "1"; If not true, to "0".

## Status Flag: SF

The Status Flag (SF) is a 1-bit flip-flop register which enables programs to conditionally skip an instruction. All instructions, including JP and CALL, are executed when SF is "1".

But if SF is "0", the program executes NOP instruction instead of JP or CALL and resets SF to "1". Then,program execution proceeds. The following instructions set the SF to "0":

## Status Flag (SF) (Continued)

MOV	@HLA	; if borrow

## Logical Instructions

NOTI A ; if (A)  $\neq$  0 after operation

## **INPUT PORTS: P0, P1**

The P0 and P1 input ports have internal pull-up 30  $-150~\rm K\Omega$  resistors, (see I/O circuit type A), each multiplexed to a common bus (see Figure 1–7). If the P2.13 pin is programmed to low, then port 0 is selected as the input port. Otherwise, if the P2.13 pin high, port 1 is selected.

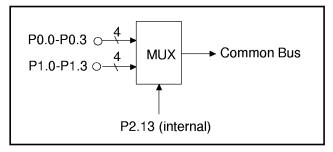

Figure 1-7. KS51840 Input Port

## **OUTPUT PORTS: P2, P3**

The P2 and P3 output ports can be configured as push-pull (P2.0/REM only) and open drain (P2.1-P2.6, P3.0-P3.3) as follows:

- Standard push-pull: A CMOS push-pull buffer with N-channel transistor to ground in conjunction with a P-channel transistor to VDD, compatible with CMOS and TTL. (see I/O Circuit Type B).
- N-channel open drain: An N-channel transistor to ground, compatible with CMOS and TTL. (see I/O Circuit Type C and D).
   P2.2-P2.5 and P3.0-P3.3 pins become low state in halt mode.

The L register specifies P2 output pins (P2.0/REM-P2.6, P2.9-P2.10, P2.12, and P2.13) individually as follows:

- SETB P2.(L): Set port 2 bits to correspond to L- register contents.
- CLRB P2.(L): Clear port 2 bits to correspond to L- register contents.

P3 output pins P3.0-P3.3 are parallel output pins.

For the KS51840, only the 4-bit accumulator outputs its value to the P3 port by the output instruction "OUT P3, @SL+A" (the value of the Status Latch (SL) does not matter).

## TRANSMISSION CARRIER FREQUENCY

One of four carrier frequencies can be selected and transmitted through the P2.0/REM pin by programming the internal P2.9, P2.10 and P2.0 pins (see Table 1–1). Figure 1–8 shows a simplified diagram of the various transmission circuits.

P2.10	P2.9	Carrier Frequency of P2.0/REM Pin
0	0	Fxx/12, 1/3 duty
0	1	Fxx/8, 1/2 duty
1	0	Fxx/12, 1/4 duty
1	1	No carrier

Table 1–1 Carrier Frequency Selection Table

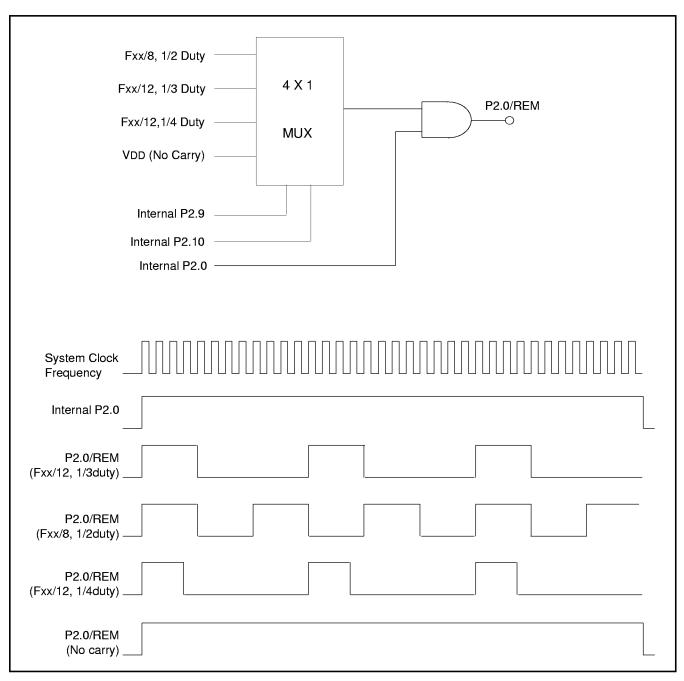

Figure 1–8. Diagram of Transmission Circuits

#### HALT MODE

The HALT mode is used to reduce power consumption by stopping the clock and holding the states of all internal operations fixed. This mode is very useful in battery-powered instruments. It also holds the controller in wait status for external stimulus to start some event. The KS51840 can be halted by programming the P2.12 pin high, and by forcing P0 input pins (P0.0-P0.3) to high and P1 input pins (P1.0- P1.3) to high, concurrently (see Figure 1–9). When in HALT mode, the internal circuitry does not receive any clock signal, and all P2, P3 output pins become low states. However, P2.1 and P2.6 pins retain their programmed values until the device is re-started as follows:

 Forcing any P0 and P1 input pins to low: system reset occurs and it continues to operate from the reset address.

An oscillation stabilization time of 13 msec in Fxx=455 KHz crystal oscillation is needed for stability (see Figure 1–10).

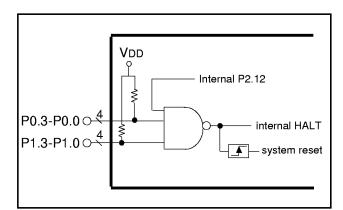

Figure 1-9. Block Diagram of HALT Logic

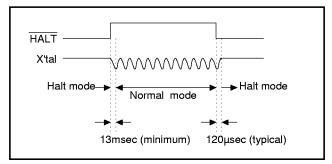

Figure 1–10. Release Timing for HALT or RESET to Normal Mode in Crystal Oscillation

#### RESET

All reset operations are internal in the KS51840. It has an internal power-on reset circuit consisting of a 7 pF capacitor, a 1M $\Omega$  resistor, and a Schmitt Trigger (see Figure 1–11). The controller also contains an auto-reset circuit that resets the chip every 131,072 oscillator clock cycles (288 ms at a Fxx=455KHz clock frequency). The auto-reset counter is cleared by the rising edge of a internal P2.0 pin, by HALT, or by the power-on reset pulse (see Figure 1-12). Therefore, no clocks are sent to the counter and the time-out is suspended in HALT mode. When a reset occurs during program execution, a transient condition occurs. The PA register is immediately initialized to 0FH. The PC, however, is not reset to 0H until one instruction cycle later. For example, if PC is 1AH when a reset pulse is generated, the instruction at 0F1AH is executed. followed by the instruction at 0F00H.

After a reset, approximately 13 msec is needed before program execution proceeds (assuming Fxx=455 KHz ceramic oscillation).

Upon initialization, registers are set as follows:

- PC register to 0 in next instruction cycle
- PA and PB registers to 0FH (15th page)
- SF and SL registers to 1
- H,L registers to unknown state
- All internal/external output pins (P3.0-P3.3, P2.0/REM-P2.6, P2.9, P2.10, P2.12 and P2.13) to low

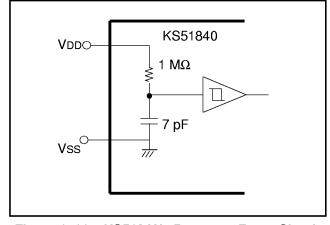

Figure 1-11. KS51840's Power-on Reset Circuit

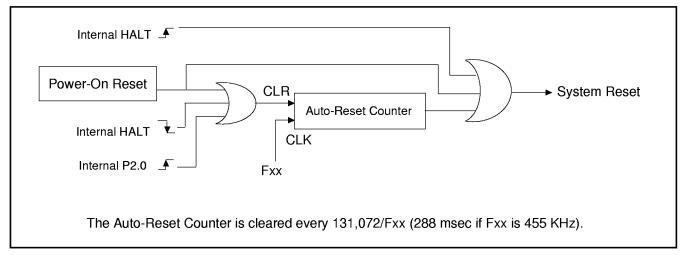

Figure 1–12. Auto Reset Block Diagram

#### **OSC DIVIDE OPTION CIRCUIT**

The OSC Divide Option Circuit provides a maximum 1MHz Fxx system clock. Fosc which is generated in oscillation circuit is divided eight or non-divided in this circuit to produce Fxx. This dividing ratio will be chosen by mask option. (see Figure 1–13)

Fosc: Oscillator clock

Fxx : System clock ( Fosc or Fosc/8)
Fcpu : CPU clock (Fcpu = Fxx/6)
1 instruction cycle clock

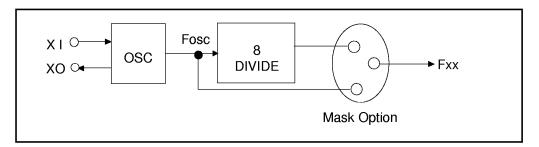

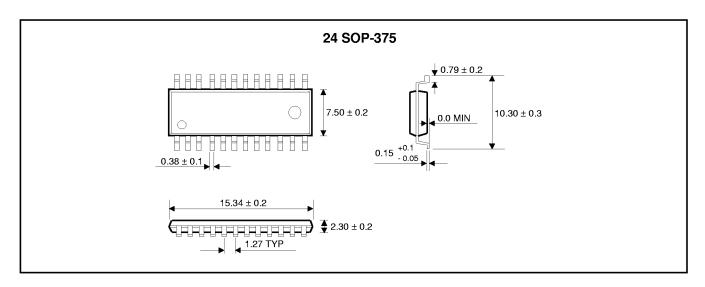

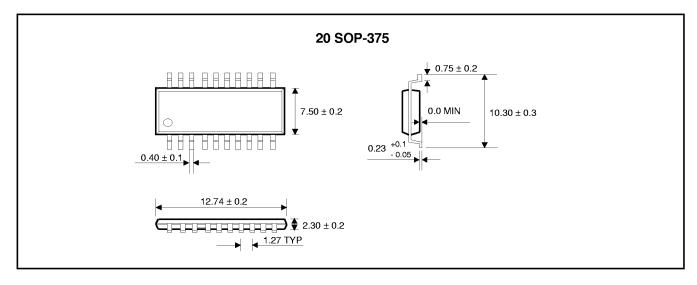

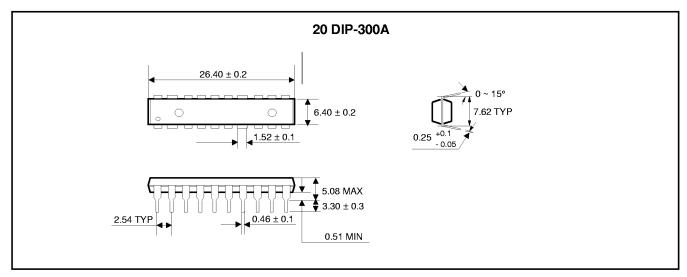

Figure 1-13 KS51840 OSC Divide Option Circiut

#### **PACKAGE DIMENSIONS**

#### **DESCRIPTION**

KS51845, a 4-bit single-chip CMOS microcontroller, consists of the reliable SMCS-51 CPU core with on-chip ROM and RAM. 6 input pins and 9 output pins provide the flexibility for various I/O requirements. Auto reset circuit generates reset pulse every certain period, and every halt mode termination time. The KS51845 microcontroller has been designed for use in small system control applications that require a low-power, cost-sensitive design solution. In addition, the KS51845 has been optimized for remote control transmitter.

#### **FUNCTIONAL DESCRIPTION**

#### **Program Memory (ROM)**

The KS51845's program memory consists of a 512-byte ROM, organized in 8 pages. Each page is 64 bytes long. (See Figure 2–3).

ROM addressing is supported by a 10-bit register made up of two sub-registers: a 4-bit Page Address register (PA), and a 6-bit Program Counter (PC).

Pages 0 through 6 and page15(FH) can each access 64 (3FH) bytes.

ROM addressing occurs as follows: The 10-bit register selects one of the ROM's 512-bytes. A new address is then loaded into the PC register during each instruction cycle.

Unless a transfer-of- control instruction such as JP, CALL, or RET is encountered, the PC is loaded with the next sequential 6-bit address in the page, PC + 1. In this case, the next address of 3FH would be 00H.

Only the PAGE instruction can change the Page Buffer (PB) to a specified value.

When a JP or CALL instruction is executed, and if the Status Flag is set to "1", the contents of the PB are loaded into the PA register. If the Status Flag is "0", however, the JP or CALL is executed like NOP instruction in an instruction cycle and the Status Flag is set to "1". After that, program execution proceeds.

## Page-In Addressing

All instructions, including JP and CALL, can be executed by page. (See Figure 2–1). When the Status Flag is "1", a JP or CALL causes a program to branch to its address (operand) in a page.

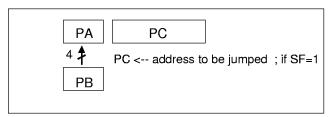

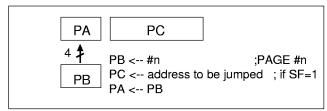

Figure 2-1. Page-In Addressing

## ■ Page-To-Page Addressing

When a PAGE instruction occurs, and if the Status Flag is "1", a JP or CALL instruction will cause a program to branch to its address (operand) across the page (see Figure 2–2).

NOTE: If SF = 0 then PC < -- PC + 1.

Figure 2–2. Page-To-Page Addressing

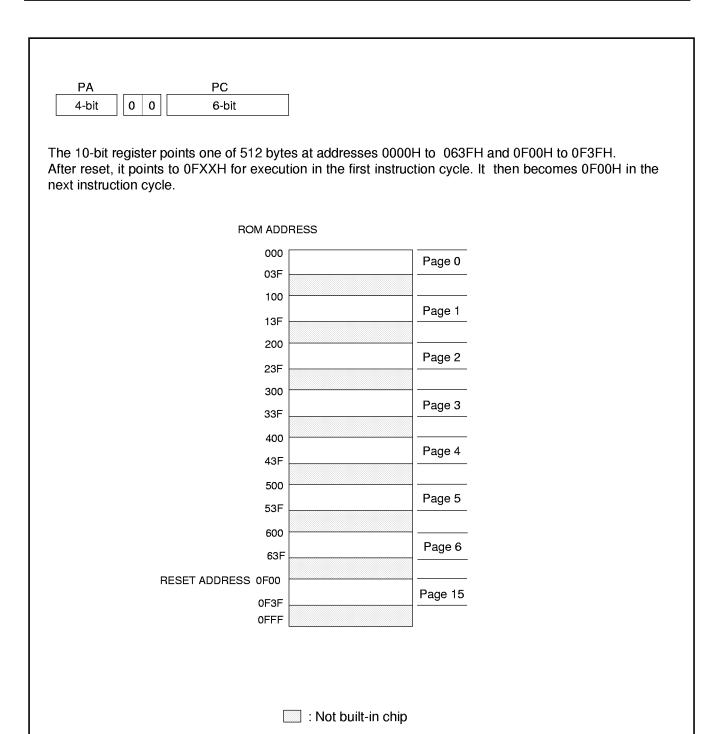

Figure 2-3. KS51845 Program Memory Map

## **Data Memory (RAM)**

The KS51845's data memory consists of a 32-nibble RAM which is organized into two files of 16 nibbles each (see Figure 2–4).

RAM addressing is implemented by a 7-bit register, HL.

Its upper 3-bit register (H) selects one of two files and its lower 4-bit register (L) selects one of 16 nibbles in the selected file.

Instructions which manipulate the H and L registers are as follow :

#### Select a file:

MOV H,#n ; H <-- #n, where n must be 0,4</li>
 NOT H ; Complement MSB of H register

#### Select a nibble in a selected file:

MOV L,A ; L <-- A</li>MOV L,@HL ; L <-- M(H,L)</li>

MOV L,#n ; L <-- #n, where 0 ≤ n ≤0FH</li>

INCS L ; L <-- L+1</li>DECS L ; L <-- L-1</li>

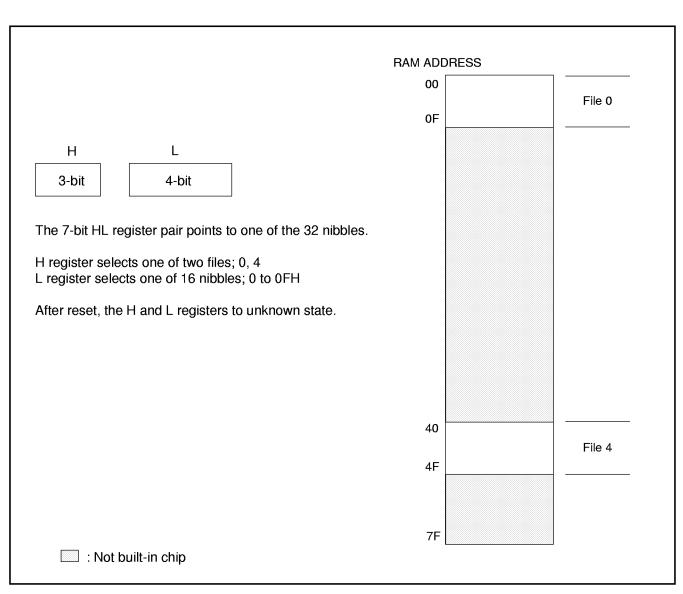

Figure 2-4. KS51845 Data Memory Map

#### **REGISTER DESCRIPTIONS**

## Stack Register (SR)

Three levels of subroutine nesting are supported by a three-level stack as shown in Figure 2–5.

Each subroutine call (CALL) pushes the next PA and PC address into the stack. The latest stack to be stored will be overwritten and lost. Each return instruction (RET) pops the stack back into the PA and PC registers.

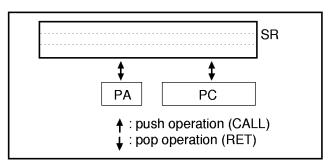

Figure 2-5. Stack Operations

## Page Address Register (PA), Page Buffer Register (PB)

The Page Address Register (PA) and Page Buffer Register (PB) are 4-bit registers. The PA always specifies the current page.

A page select instruction (PAGE #n) loads the value "n" into the PB. When JP or CALL instruction is executed, and if the Status Flag (SF) is set to 1, the contents of PB are loaded into PA. If SF is "0", however, the JP or CALL is executed like NOP instruction and SF is set to "1". The contents of PB don't be loaded. Figure 2–6 illustrates this concept.

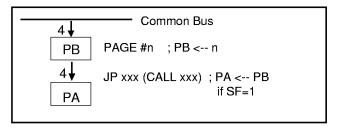

Figure 2-6. PA, PB Operations

## Arithmetic Logic Unit (ALU), Accumulator (A)

The SMCS-51 CPU contains an ALU and its own 4-bit register (accumulator) which is the source and destination register for most I/O, arithmetic, logic, and data memory access operations.

Arithmetic functions and logical operations will set the status flag (SF) to "0" or "1".

## Status Latch (SL)

The Status Latch (SL) flag is an 1-bit flip-flop register. Only the "CPNE L,A" instruction can change the value of SL.

If the result of a "CPNE L,A" instruction is true, the SL is set to "1"; If not true, to "0".

#### Status Flag: SF

The Status Flag (SF) is a 1-bit flip-flop register which enables programs to conditionally skip an instruction. All instructions, including JP and CALL, are executed when SF is "1".

But if SF is "0", the program executes NOP instruction instead of JP or CALL and resets SF to "1". Then,program execution proceeds. The following instructions set the SF to "0":

## Status Flag (SF) (Continued)

#### Arithmetic Instructions

ADDS	A,#n	; if no carry
ADDS	A,@HL	; if no carry
INCS	A,@HL	; if no carry
INCS	Α	; if no carry
INCS	L	; if no carry
SUBS	A,@HL	; if borrow
DECS	A,@HL	; if borrow
DECS	Α	; if borrow
DECS	L	; if borrow

#### Compare Instructions

CPNE	@HL,A	; if M(H,L)=(A)
CPNZ	@HL	; if M(H,L)=0
CPNE	L,#n	; if (L)=#n
CPNE	L,A	; if (L)=(A)
CPLE	A,@HL	; if (A)>M(H,L)
CPNZ	P0	; if (P0)=0
CPBT	@HL,b	; if M(H,L).b≠1

#### Data Transfer Instructions

MOV	@HL+,A	; if no carry
MOV	@HL-,A	; if borrow

## Logical Instructions

NOTI A ; if (A)  $\neq$  0 after operation

## **INPUT PORTS: P0, P1**

The P0 and P1 input ports have internal pull-up  $30-150~\mathrm{K}\Omega$  resistors, (see I/O circuit type A), each multiplexed to a common bus (see Figure 2–7). If the P2.13 pin is programmed to low, then port 0 is selected as the input port. Otherwise, if the P2.13 pin high, port 1 is selected.

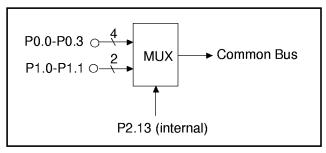

Figure 2–7. KS51845 Input Port

#### **OUTPUT PORTS: P2, P3**

The P2 and P3 output ports can be configured as push-pull (P2.0/REM only) and open drain (P2.1-P2.4, P3.0-P3.3) as follows:

- Standard push-pull: A CMOS push-pull buffer with N-channel transistor to ground in conjunction with a P-channel transistor to VDD, compatible with CMOS and TTL. (see I/O Circuit Type B).
- N-channel open drain: An N-channel transistor to ground, compatible with CMOS and TTL. (see I/O Circuit Type C and D).
   P2.2-P2.4 and P3.0-P3.3 pins become low state in halt mode.

The L register specifies P2 output pins (P2.0/REM-P2.4, P2.9-P2.10, P2.12, and P2.13) individually as follows:

- SETB P2.(L): Set port 2 bits to correspond to L- register contents.
- CLRB P2.(L): Clear port 2 bits to correspond to L- register contents.

P3 output pins P3.0-P3.3 are parallel output pins.

For the KS51845, only the 4-bit accumulator outputs its value to the P3 port by the output instruction "OUT P3, @SL+A" (the value of the Status Latch (SL) does not matter).

# TRANSMISSION CARRIER FREQUENCY

One of four carrier frequencies can be selected and transmitted through the P2.0/REM pin by programming the internal P2.9, P2.10 and P2.0 pins (see Table 2–1). Figure 2–8 shows a simplified diagram of the various transmission circuits.

P2.10	P2.9	Carrier Frequency of P2.0/REM Pin
0	0	Fxx/12, 1/3 duty
0	1	Fxx/8, 1/2 duty
1	0	Fxx/12, 1/4 duty
1	1	No carrier

Table 2–1 Carrier Frequency Selection Table

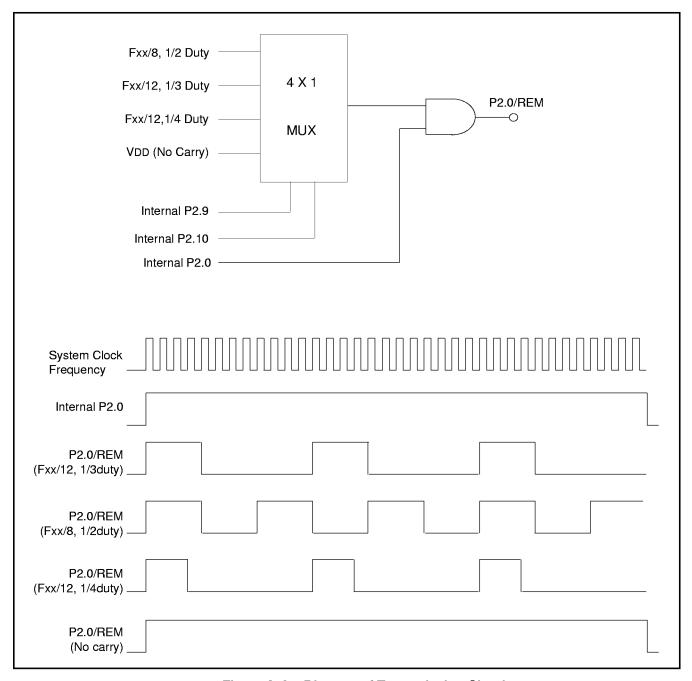

Figure 2–8. Diagram of Transmission Circuits

#### **HALT MODE**

The HALT mode is used to reduce power consumption by stopping the clock and holding the states of all internal operations fixed. This mode is very useful in battery-powered instruments. It also holds the controller in wait status for external stimulus to start some event. The KS51845 can be halted by programming the P2.12 pin high, and by forcing P0 input pins (P0.0 –P0.3) to high and P1 input pins (P1.0 – P1.1) to high, concurrently (see Figure 2–9). When in HALT mode, the internal circuitry does not receive any clock signal, and all P2, P3 output pins become low states. However, P2.1 pin retains its programmed value until the device is re-started as follows:

 Forcing any P0 and P1 input pins to low: system reset occurs and it continues to operate from the reset address.

An oscillation stabilization time of 13 msec in Fxx=455 KHz crystal oscillation is needed for stability (see Figure 2–10).

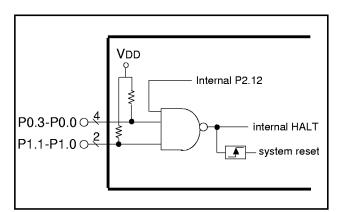

Figure 2-9. Block Diagram of HALT Logic

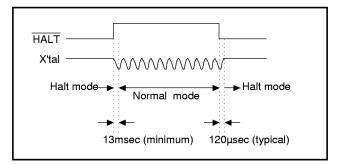

Figure 2–10. Release Timing for HALT or RESET to Normal Mode in Crystal Oscillation

#### RESET

All reset operations are internal in the KS51845. It has an internal power-on reset circuit consisting of a 7 pF capacitor, a  $1M\Omega$  resistor, and a Schmitt Trigger (see Figure 2-11). The controller also contains an auto-reset circuit that resets the chip every 131,072 oscillator clock cycles (288 ms at a Fxx=455KHz clock frequency). The auto-reset counter is cleared by the rising edge of a internal P2.0 pin, by HALT, or by the power-on reset pulse (see Figure 2-12). Therefore, no clocks are sent to the counter and the time-out is suspended in HALT mode. When a reset occurs during program execution, a transient condition occurs. The PA register is immediately initialized to 0FH. The PC, however, is not reset to 0H until one instruction cycle later. For example, if PC is 1AH when a reset pulse is generated, the instruction at 0F1AH is executed, followed by the instruction at 0F00H.

After a reset, approximately 13 msec is needed before program execution proceeds (assuming Fxx=455 KHz ceramic oscillation).

Upon initialization, registers are set as follows:

- PC register to 0 in next instruction cycle
- PA and PB registers to 0FH (15th page)
- SF and SL registers to 1
- H,L registers to unknown state.
- All internal/external output pins (P3.0-P3.3, P2.0/REM-P2.4, P2.9, P2.10, P2.12 and P2.13) to low

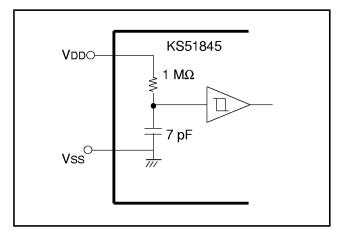

Figure 2-11. KS51845's Power-on Reset Circuit

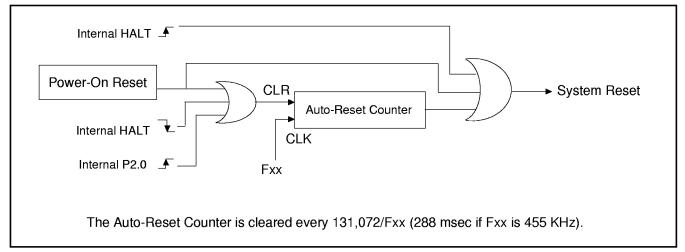

Figure 2-12. Auto Reset Block Diagram

#### **OSC DIVIDE OPTION CIRCUIT**

The OSC Divide Option Circuit provides a maximum 1MHz Fxx system clock. Fosc which is generated in oscillation circuit is divided eight or non-divided in this circuit to produce Fxx. This dividing ratio will be chosen by mask option. (see Figure 2–13)

Fosc : Oscillator clock

Fxx : System clock ( Fosc or Fosc/8)
Fcpu : CPU clock (Fcpu = Fxx/6)
1 instruction cycle clock

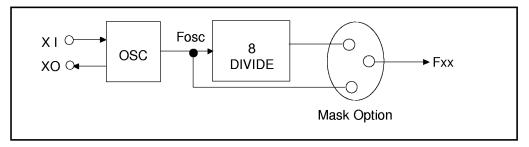

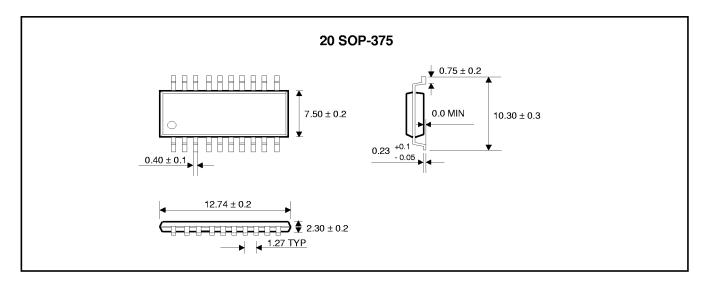

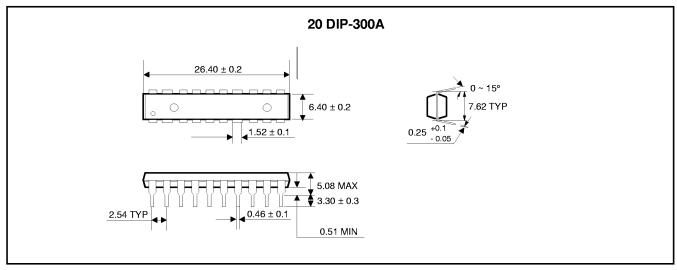

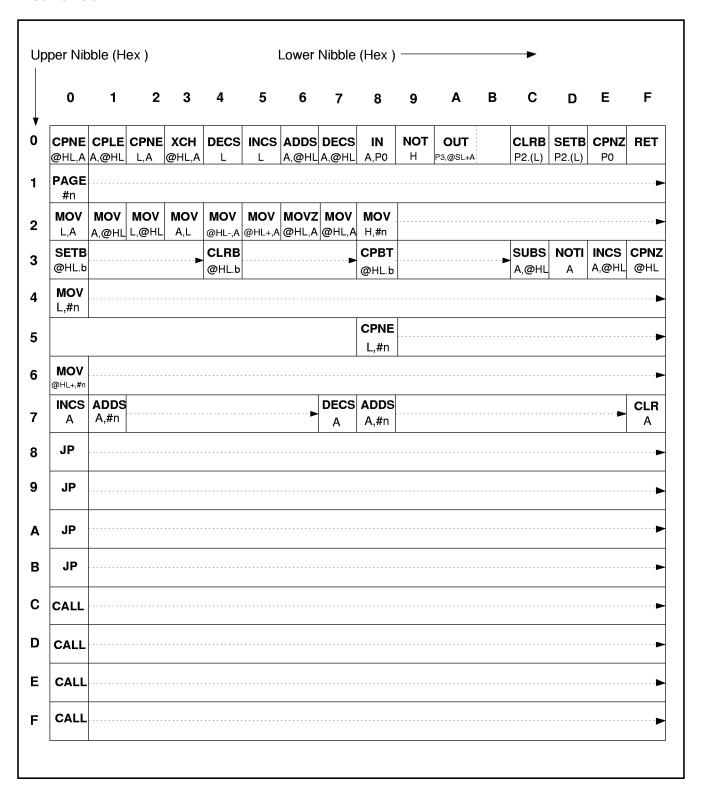

Figure 2-13 KS51845 OSC Divide Option Circiut

## **PACKAGE DIMENSIONS**

#### **KS51 OPCODE MAP**

## **INSTRUCTION SET**

## MOV L,A

Binary Code: 0 0 1 0 0 0 0 0

Description: The contents of the accumulator are moved to register L.

The contents of the source operand are not affected.

Operation:  $(L) \leftarrow (A)$ 

Flags: SF: Set to one

SL: Unaffected

Example: CLR A ; Clear the contents of A

MOV L,A ; Move 0H to REG L

## MOV A,L

Binary Code: 0 0 1 0 0 0 1 1

Description: The contents of register L are moved to the accumulator.

The contents of the source operand are not affected.

Operation:  $(A) \leftarrow (L)$ 

Flags: SF: Set to one

SL: Unaffected

Example: MOV L,#3H; Move 3H to REG L

MOV A,L ; Move 3H to A

#### MOV @HL,A

Binary Code: 0 0 1 0 0 1 1 1

Description: The contents of the accumulator are moved to the data memory whose address is specified by

registers H and L.

The contents of the source operand are not affected.

Operation:  $M[(H,L)] \leftarrow (A)$ 

Flags: SF: Set to one

SL: Unaffected

Example: CLR A ; Clear the contents of A

MOV H,#0H ; Move 0H to REG H MOV L,#3H ; Move 3H to REG L

MOV @HL,A ; Move 0H to RAM address 03H

## MOV A,@HL

Binary Code: 0 0 1 0 0 0 0 1

Description: The contents of the data memory addressed by registers H and L are moved to accumulator.

The contents of the source operand are not affected.

Operation:  $(A) \leftarrow M[(H,L)]$ 

Flags: SF: Set to one

SL: Unaffected

Example: Assume HL contains 04H

MOV A,@HL ; Move contents of RAM address 04H to A

#### MOV L,@HL

Binary Code: 0 0 1 0 0 0 1 0

Description: The contents of the data memory addressed by registers H and L are moved to register L.

The contents of the source operand are not affected.

Operation :  $(L) \leftarrow M[(H,L)]$ 

Flags: SF: Set to one

SL: Unaffected

Example: Assume HL contains 04H

MOV L,@HL ; Move contents of RAM address 4H to REG L

CPNE L,#5H ; Compare 5H to REG L values
JP XX ; Jump to XX if REG L value is not 5H
JP YY ; Jump to YY if REG L value is 5H

## MOV @HL+,A

Binary Code: 0 0 1 0 0 1 0 1

Description: The contents of the accumulator are moved to the data memory addressed by registers H, L;

L register contents are incremented by one.

The contents of the source operand are not affected.

Operation :  $M[(H,L)] \leftarrow (A), L \leftarrow L + 1$ 

Flags: SF: Set if carry occurs; cleared otherwise

SL: Unaffected

Example: MOV H,#0H

MOV L,#0FH CLR A

MOV @HL+.A ; Move 0H to RAM address 0FH and increment REG L value by one

JP PRT ; Jump to PRT, since there is a carry from increment

#### **INSTRUCTION SET**

#### MOV @HL-,A

Binary Code: 0 0 1 0 0 1 0 0

Description: The contents of accumulator are moved to the data memory addressed by registers H, L;

L register contents are decremented by one.

The contents of the source operand are not affected.

Operation :  $M[(H,L)] \leftarrow (A), L \leftarrow L - 1$ 

Flags: SF: Set if no borrow; cleared otherwise

SL: Unaffected

Example: MOV H,#0H

MOV L,#3H CLR A MOV @HL-,A JP ABC

## MOV L,#n

Binary Code: 0 1 0 0 d d d d

Description: The 4-bit value specified by n (data) is loaded into register L.

The contents of the source operand are not affected.

Operation: (L) <-- #n

Flags: SF: Set to one

SL: Unaffected

Example: MOV L,#8H ; 8H is moved to REG L

## MOV H,#n

Binary Code: 0 0 1 0 1 d d d

Description: The 3-bit value specified by n (data) is moved to register H.

The contents of the source operand are not affected.

Operation: (H) <-- #n

Flags: SF: Set to one

SL: Unaffected

Example: MOV H,#4H ; 4H is moved into REG H

#### MOV @HL+,#n

Binary Code: 0 1 1 0 d d d d

Description: The 4-bit value specified by n (data) is moved to data memory addressed by registers H, L;

L register contents are incremented by one.

The contents of the source operand are not affected.

Operation : M[(H,L)] < -- #n, L < -- L + 1

Flags: SF: Set to one

SL: Unaffected

Example: MOV H,#0H

MOV L,#7H

MOV @HL+,#9H ; Move 9H to RAM address 07H and increment REG L value by one,

then REG L contains 8H

#### MOVZ @HL,A

Binary Code: 0 0 1 0 0 1 1 0

Description: The contents of the accumulator are moved to the data memory addressed by registers H, L;

accumulator contents are cleared to zero.

Operation : M[(H,L)] < --(A), (A) < --0

Flags: SF: Set to one

SL: Unaffected

Example: MOV L,#3H

MOV A,L

MOVZ @HL,A ; Move 3H to indirect RAM and clear A to zero

MOV L,A ; Move 0H to REG L SETB P2.(L) ; Set P2.0 to 1

#### XCH @HL,A

Binary Code: 0 0 0 0 0 1 1

Description: This instruction exchanges the contents of the data memory addressed by registers H and L with

the accumulator contents.

Operation: M[(H,L)] <--> (A)

Flags: SF: Set to one

SL: Unaffected

Example: MOV H,#0H

MOV L,#6H

CLR A ; Clear A to zero ADDS A,#5H ; Add 5H to A

XCH @HL,A ; Exchange 5H with contents of RAM address 06H

#### **INSTRUCTION SET**

PAGE #n

Binary Code: 0 0 0 1 d d d d

Description: The immediate 4-bit value specified by n (data) is loaded into the PB register.

Operation: (PB) <-- #n

Flags: SF: Set to one

SL: Unaffected

Example: PAGE #3H ; Move 3H to page buffer

JP AN ; Jump to label AN located at page 3 if SF is one;

otherwise, it is skipped

CPNE @HL,A

Binary Code : 0 0 0 0 0 0 0 0

Description: The contents of accumulator are compared to the contents of indirect data memory; an appropriate

flag is set if their values are not equal.

The contents of both operands are unaffected by the comparison.

Operation:  $M[(H,L)] \neq (A)$ 

Flags: SF: Set if not equal, cleared otherwise

SL: Unaffected

Example: CLR A

ADDS A,#3H MOV H,#0H MOV L,#6H

CPNE @HL,A ; Acc value 3H is compared to contents of RAM address 06H JP OA ; Jump to OA if values of RAM address 06H are not 3H JP OB ; Jump to OB if values of RAM address 06H are 3H

CPNZ @HL

Binary Code: 0 0 1 1 1 1 1 1 1

Description: This instruction compares the magnitude of indirect data memory with zero, and the appropriate

flag is set if their values are not equal, i.e., if the contents of indirect data memory are not zero.

The contents of operand are unaffected by the comparison.

Operation:  $M[(H,L)] \neq 0$ 

Flags: SF: Set if not zero, cleared otherwise

SL: Unaffected

Example: ; Assume the contents of RAM address are 4H

CPNZ @HL ; Compare 4H with zero

JP EQ ; Jump to EQ because the result is not equal

JP WAIT

CPNE L,A

Binary Code: 0 0 0 0 0 1 0

Description: The contents of the accumulator are compared to the contents of register L; the appropriate flags

are set if their values are not equal.

The contents of both operands are unaffected by the comparison.

Operation:  $(L) \neq (A)$ 

Flags: SF: Set if not equal, cleared otherwise

SL: Set if not equal, cleared otherwise

Example: ; Assume REG L contains 5H, A contains 4H

CPNE L,A ; Compare A to REG L values

JP K1 ; Jump to K1 because the result is not equal

JP K2

CPNE L,#n

Binary Code: 0 1 0 1 d d d d

Description: This instruction compares the immediate 4 bit data n with the contents of register L, and sets an

appropriate flag if their values are not equal.

The contents of both operands are unaffected by the comparison.

Operation:  $(L) \neq #n$ 

Flags: SF: Set if not equal, cleared otherwise

SL: Unaffected

Example: CLR A

ADDS A,#4H MOV L,A

CPNE L,#5H ; Compare immediate data 5H to REG L values JP K3 ; Jump to K3 because the result is not equal

CPLE A,@HL

Binary Code: 0 0 0 0 0 0 1

Description: The contents of indirect data memory are compared to the contents of the accumulator.

Appropriate flags are set if the contents of the accumulator are less than or equal to the contents

of indirect data memory.

The contents of both operands are unaffected by the comparison.

Operation :  $(A) \le M [(H,L)]$ 

Flags: SF: Set if less than or equal to, cleared otherwise

SL: Unaffected

Example: Assume RAM address holds 8H

CPLE A,@HL ; Compare 8H to A values JP MAR ; Jump to MAR if  $0H \le A \le 8H$  JP BPR ; Jump to BPR if  $9H \le A \le 0FH$ 

## **INSTRUCTION SET**

#### CPNZ P0

Binary Code: 0 0 0 0 1 1 1 0

Description: This instruction compares the contents of Port 0 with zero. Appropriate flags are set if their

values are not equal, i.e., if the contents of Port 0 are not zero. The contents of the operand are unaffected by the comparison.

Operation:  $(P0) \neq 0$ 

Flags: SF: Set if not zero, cleared otherwise

SL: Unaffected

Example: MOV L,#0DH

CLRB P2.(L) ; Clear P2.13, i.e., select P0 input

CPNZ P0 ; Compare P0 to zero JP KEYIN ; Jump to KEYIN if P0  $\neq$  0 JP NOKEY ; Jump to NOKEY if P0 = 0

## CPBT @HL.b

Binary Code: 0 0 1 1 1 0 d d

Description: CPBT tests indirect data memory bit and sets appropriate flags if the bit value is one.

The contents of operand are unaffected by the test.

Operation: M[(H,L,b)] = 1

Flags: SF: Set if one, cleared otherwise

SL: Unaffected

Example: MOV H,#0H

MOV L,#0BH

CPBT @HL.3 ; Test RAM address 0BH bit 3
JP Q1 ; Jump to Q1 if RAM address bit 3 is 1
JP Q2 ; Jump to Q2 if RAM address bit 3 is 0

#### JP dst

Binary Code: 1 0 d d d d d d

Description: The JP transfers program control to the destination address if the SF is one.

The conditional jump replaces the contents of the program counter with the address indicated and

transfers control to that location.

Had the SF flag not been set, control would have proceeded with the next instruction.

Operation : If SF=1 ; PC <-- I (W), PA <-- PB

Flags: SF: Set to one

SL: Unaffected

Example: JP SUTIN1; This instruction will cause program execution to branch to the

instruction at label SUTIN1; SUTIN1 must be within the

current page

#### CALL dst

Binary Code: 11ddddddd

Description: If the SF flag is set to 1, this instruction calls a subroutine located at the indicated address, and

then pushes the current contents of the program counter to the top of the stack. The program counter value used is the address of the first instruction following the CALL instruction. The specified destination address is then loaded into the program counter and points to the first instruction of a procedure. At the end of the procedure, the return (RET) instruction can be used

to return to the original program flow.

Operation: If SF=1; SRi <-- PC + 1, PSRi <-- PA

PC <-- I (W), PA <-- PB

Flags: SF: Set to one

SL: Unaffected

Example: CALL ACD1 ; CALL subroutine located at the label ACD1 where ACD1 must be

within the current page

#### **RET**

Binary Code: 0 0 0 0 1 1 1 1

Description: This instruction is normally used to return to the previously executing procedure at the end of a

procedure entered by a CALL instruction. The contents of the location addressed by the stack pointer are popped into the program counter. The next statement executed is that addressed by

the new contents of the program counter.

Operation: PC <-- SRi, PB <-- PSRi

PA <-- PB

Flags: SF: Set to one

SL: Unaffected

Example: RET ;Return from subroutine

## SETB P2.(L)

Binary Code: 0 0 0 0 1 1 0 1

Description: This instruction sets the Port 2 bit addressed by register L without affecting any other bits in the

destination.

Operation: P2.(L) <-- 1

Flags: SF: Set to one

SL: Unaffected

Example: MOV L,#0H

SETB P2.(L) ; Set P2.0 to 1

## **INSTRUCTION SET**

CLRB P2.(L)

Binary Code: 0 0 0 0 1 1 0 0

Description: This instruction clears the Port 2 bit addressed by register L without affecting any other bits in the

destination.

Operation: P2.(L) <-- 0

Flags: SF: Set to one

SL: Unaffected

Example:

MOV L,#0H

CLRB P2.(L) ; Clear P2.0 to 0

IN A,P0

Binary Code: 0 0 0 0 1 0 0 0

Description: Data present on Port n is transferred (read) to the accumulator.

Operation: (A) < -- (Pn) (n=0, 1)

Flags: SF: Set to one

SL: Unaffected

Example: IN A,P0; Input port 0 data to Acc

MOV L,A

CPNE L,#3H

JP OX ; Jump to OX if port 0 data  $\neq$  3H JP QP ; Jump to QP if port 0 data = 3H

OUT P3,@SL+A

Binary Code: 0 0 0 0 1 0 1 0

Description: The contents of the accumulator and SL are transferred to the P3 Output register.

Operation: (P3 Output register) <-- (A) + (SL)

Flags: SF: Set to one

SL: Unaffected

Example: CLR A

OUT P3,@SL+A ; Zero output on port 3

# NOTI A

Binary Code: 0 0 1 1 1 1 0 1

Description: The contents of the accumulator are complemented; all 1 bits are changed to 0, and vice-versa,

and then incremented by one.

Operation:  $(A) \leftarrow \overline{(A)}, (A) \leftarrow (A) + 1$ 

Flags: SF: Set if the result is zero, cleared otherwise

SL: Unaffected

Example: CLR A

ADDS A,#7H

NOTI A ; Complement 7H (0111B) and increment the result by one; the

instruction NOTI A then leaves 9H (1001B) in A

## NOT H

Binary Code: 0 0 0 0 1 0 0 1

Description: The MSB of register H is complemented.

Operation:  $(H) \leftarrow \overline{(H)}$ 

Flags: SF: Set to one

SL: Unaffected

Example: MOV H,#4H

NOT H ; Complement 4H (100B), then it leaves 00H (000B) in REG H

#### **INSTRUCTION SET**

#### CLR A

Binary Code: 0 1 1 1 1 1 1 1

Description: The contents of the accumulator are cleared to zero (all bits set on zero).

Operation: (A) <-- 0

Flags: SF: Set to one

SL: Unaffected

Example: CLR A ; A values are cleared to zero

## ADDS A,@HL

Binary Code: 0 0 0 0 0 1 1 0

Description: ADDS adds the contents of indirect data memory to accumulator, leaving the result in the

accumulator.

The contents of the source operand are unaffected.

Operation :  $(A) \leftarrow M[(H,L)] + (A)$ 

Flags: SF: Set if a carry occurred, cleared otherwise

SL: Unaffected

Example: Assume RAM address holds 5H

CLR A ; Clear A to zero

ADDS A,@HL ; This instruction will leave 5H in A

## ADDS A,#n

Binary Code: 0 1 1 1 d d d d

Description: The specified 4-bit data n is added to the accumulator and the sum is stored in the accumulator.

Operation:  $(A) \leftarrow (A) + \#n$ 

Flags: SF: Set if a carry occurred, cleared otherwise

SL: Unaffected

Example : CLR A ; Clear A to zero

ADDS A,#4H; Add 4H to A, it leaves 4H in A

SUBS A,@HL

Binary Code: 0 0 1 1 1 1 0 0

Description: SUBS subtracts the contents of accumulator from the contents of indirect data memory, leaving

the result in the accumulator.

The contents of source operand are unaffected.

Operation:  $(A) \leftarrow M[(H,L)] - (A)$ 

Flags: SF: Set if no borrow occurred, cleared otherwise

SL: Unaffected

Example: Assume RAM address holds 0CH

MOV L,#8H MOV A,L

SUBS A,@HL ; Subtract A from 0CH ; it will leave 4H in A

INCS A,@HL

Binary Code: 0 0 1 1 1 1 1 0

Description: The contents of indirect data memory are incremented by one and the result is loaded into the

accumulator.

The contents of indirect data memory are unaffected.

Operation:  $(A) \leftarrow M[(H,L)] + 1$ 

Flags: SF: Set if a carry occurred, cleared otherwise

SL: Unaffected

Example: Assume RAM address holds 6H

CLR A ; Clear A to zero

INCS A,@HL ; Increment 6H by one and leave 7H in A

INCS L

Binary Code: 0 0 0 0 0 1 0 1

Description: The contents of the L register are incremented by one.

Operation:  $(L) \leftarrow (L) + 1$ 

Flags: SF: Set if a carry occurred, cleared otherwise

SL: Unaffected

Example: MOV L,#5H

INCS L ; Increment REG L value 5H by one

## **INSTRUCTION SET**

#### INCS A

Binary Code: 0 1 1 1 0 0 0 0

Description: The contents of the accumulator are incremented by one.

Operation : (A) < -- (A) + 1

Flags: SF: Set if a carry occurred, cleared otherwise

SL: Unaffected

Example: MOV L,#5H

MOV A,L

INCS A ; Increment 5H by one

## DECS A

Binary Code: 0 1 1 1 0 1 1 1

Description: The contents of the accumulator are decremented by one.

Operation: (A) <-- (A) - 1

Flags: SF: Set if no borrow occurred, cleared otherwise

SL: Unaffected

Example: MOV L,#0BH

MOV A,L

DECS A ; This instruction leaves the value 0AH in A

## DECS A,@HL

Binary Code: 0 0 0 0 0 1 1 1

Description: The contents of the data memory addressed by the H and L registers are decremented by one and

the result is loaded in the accumulator. But the contents of data memory are not affected.

Operation :  $(A) \leftarrow M[(H,L)] - 1$ 

Flags: SF: Set if no borrow occurred, cleared otherwise

SL: Unaffected

Example: Assume RAM address holds 5H

MOV L,#0AH

MOV A,L

DECS A,@HL ; Decrement the value 5H by one, and the result value 4H is loaded in A

DECS L

Binary Code : 0 0 0 0 0 1 0 0

Description: The contents of the L register are decremented by one.

Operation: (L) <-- (L) - 1

Flags: SF: Set if no borrow occurred, cleared otherwise

SL: Unaffected

Example: MOV L,#3H

DECS L ; This instruction leaves the value 2H in REG L

SETB @HL.b

Binary Code: 0 0 1 1 0 0 d d

Description: This instruction sets indirect data memory bit addressed by registers H and L without affecting any

other bits in the destination.

Operation: b < -1 (b=0,1,2,3)

Flags: SF: Set to one

SL: Unaffected

Example: MOV H,#0H

MOV L,#5H

SETB @HL.2 ; Set RAM address 05H bit 2 to 1

CLRB @HL.b

Binary Code: 0 0 1 1 0 1 d d

Description: This instruction clears the indirect data memory bit addressed by registers H and L without

affecting any other bits in the destination.

Operation: b < -1 (b=0,1,2,3)

Flags: SF: Set to one

SL: Unaffected

Example: MOV H,#0H

MOV L,#5H

CLRB @HL.3 ; Clear RAM address 05H bit 3 to zero

**NOTES** 

#### **SMDS**

The Samsung Microcontroller Development System, SMDS, is a complete PC-based development environment for KS51840/51845 microcontroller. The SMDS is powerful, reliable, and portable. The SMDS tool set includes a versatile debugging utility, trace with built-in logic analyzer, and performance measurement applications.

Its window-oriented program development structure makes SMDS easy to use. SMDS has three components:

- IBM PC-compatible SMDS software, all device-specific development files, and the SAMA assembler.
- Development system kit including main board, personality board, SMDS manual, and target board adapter, if required.
- Device-specific target board.

#### **SMDS Product Versions**

As of the date of this publication, two versions of the SMDS are being supported:

- SMDS Version 4.8 (S/W) and SMDS Version 3.6 (H/W); last release: January, 1994.
- SMDS2 Version 5.3 (S/W) and SMDS2 Version 1.3 (H/W); last release: November, 1995.

The new SMDS2 Version 1.3 is intended to replace the older Version 3.6 SMDS. The SMDS2 contains many enhancements to both hardware and software. These development systems are also supported by the personality boards of Samsung's microcontroller series: KS56, KS57, and KS88.

### **SAMA ASSEMBLER**

The Samsung Arrangeable Microcontroller (SAM) Assembler, SAMA, is a universal assembler, and generates object code in standard hexadecimal format.

Compiled program code includes the object code that is used for ROM data and required SMDS program control data. To compile programs, SAMA requires a source file and an auxiliary definition (DEF) file with device-specific information.

## **TARGET BOARDS and PIGGYBACKS**

Target boards are available for KS51840/51845 microcontroller. All required target system cables and adapters are included with the device-specific target board.

Piggyback chips are provided to customers in limited quantities for KS51840/51845 microcontroller. The KS51840 piggyback chips, PB51840/51845-20 and PB51840-24 are now available.

PB51840/51845-20 is 20 DIP piggyback chip for 20 DIP, 20 SOP package device of KS51840/51845 microcontroller.

PB51840-24 is 24 DIP piggyback chip for 24 SOP package device of KS51840 microcontroller.

## **TB51840/51845A TARGET BOARD**

The TB51840/51845A target board is used for the KS51840/51845 microcontroller. It is supported by the SMDS2 development system only.

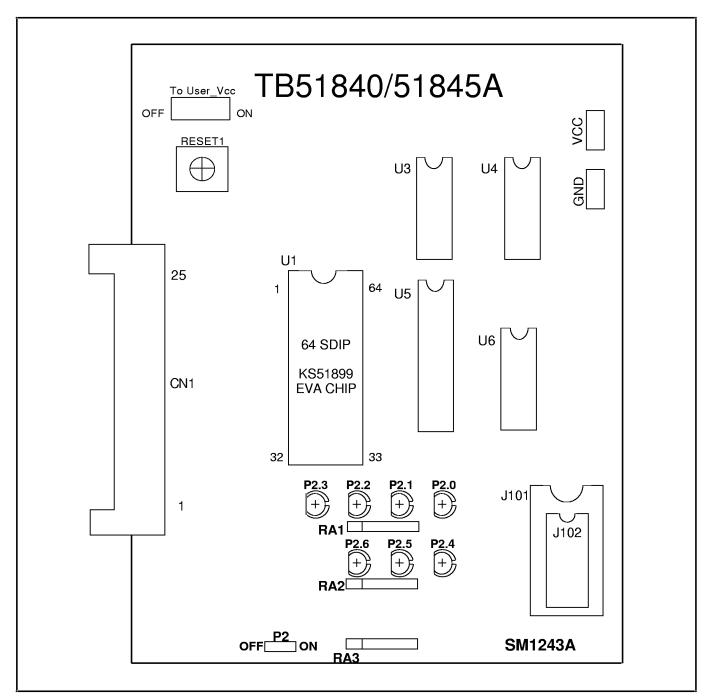

Figure 4–2. TB51840/51845A Target Board Configuration

'To User\_Vcc' Settings **Operating Mode** Comments The SMDS2 supplies V<sub>CC</sub> to the target board (evaluation To User Vcc TB51840/ **TARGET** chip) and the target system. ON 51845A **SYSTEM** VCC-VSS VCC SMDS2 The SMDS2 supplies V<sub>CC</sub> only to the target board TB51840/ To User\_Vcc (evaluation chip). The target **TARGET** 51845A OFF OOO External system must have its own **SYSTEM** VCC power supply. VSS<sup>-</sup> **VCC** SMDS2

Table 4-1. Power Selection Settings for TB51840/51845A

## LED2.0 - LED2.6:

These LEDs are used to display value of the P2.0–P2.6. It will be turn on, if the value is Low.

## **P2 OPTION SWITCH:**

Switch ON: You can see the port value using the LED display.

Switch OFF: You can't see the port value. That is, the LED won't be turn ON by the port value.

## **DESCRIPTION OF THE KS51840/51845 MCUS**

The KS51840/51845 4-bit single-chip CMOS microcontroller is designed using the reliable SMCS-51 CPU core with on-chip ROM and RAM. An auto-reset circuit generates a RESET pulse in regular intervals, and can be used to initiate a Halt mode release. The KS51840/51845 microcontroller is intended for use in small system control applications that require a low-power and cost-sensitive design solution. In addition, the KS51840/51845 has been optimized for remote control transmitters. To flexibly support various I/O requirements, the KS51840 of 24-pin has eight input pins and 11 output pins, the KS51840/51845 of 20-pin has six input pins and nine output pins.

## **FEATURES**

Table 5-1. KS51840/51845 Features

Feature	KS51840 (24-pin)	KS51840 (20-pin)	KS51845 (20-pin)	
ROM	1024 bytes	1024 bytes	512 bytes	
RAM	32 x 4 bits	32 x 4 bits	32 x 4 bits	
Output pin	11 pins	9 pins	9 pins	
Input pin	8 pins	6 pins	6 pins	
Carrier frequency	fxx/12, fxx/8, no carrier	fxx/12, fxx/8, no carrier	fxx/12, fxx/8, no carrier	
Operating voltage	Fosc: 250kHz-3.9MHz	Fosc: 250kHz-3.9MHz	Fosc: 250kHz-3.9MHz	
	1.8V to 3.6V,	1.8V to 3.6V,	1.8V to 3.6V,	
	Fosc: 4MHz–6MHz	Fosc: 4MHz–6MHz	Fosc: 4MHz–6MHz	
	2.2V to 3.6V	2.2V to 3.6V	2.2V to 3.6V	
Package	24 SOP	20 DIP, SOP	20 DIP, SOP	

Table 5-2. KS51840/51845 Functions

	Description
Automatic reset by Halt mode release	When Halt mode is released, the chip is reset after an oscillator stabilization interval of 9 ms. (Fxx=455kHz)
Output pin state retention function	When the system enters Halt mode, P3.0-P3.3, P2.0, and P2.2-P2.5 go low level in 24 pins. P3.0-P3.3, P2.0, and P2.2-P2.4 go low level in 20 pins.
Auto-reset	With oscillation on and with no change to the IP2.0 output pin, a reset is activated every 288 ms at Fxx=455 kHz.
Osc. stabilization time	CPU instructions are executed after oscillation stabilization time has elapsed.
Power-on reset circuit	Pull-up resistor: 1 MΩ, capacitor value: 7 pF.
Other functions	Carrier frequency generator. Halt wake-up function.

## **RESET**

The KS51840/51845 has three kinds of reset operations: -- POR (Power-On Reset)

- -- Auto-reset -- Automatic reset by Halt mode release

## **Power-On Reset Circuits**

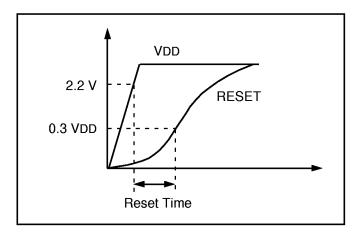

Figure 5-1. Power-On Reset Circuits

#### **Auto-Reset**

The auto-reset function resets the CPU every 131,072 oscillator cycles (288 ms at Fxx=455 kHz). The auto-reset counter is cleared when a rising edge is detected at IP2.0, or by a HALT or RESET pulse.

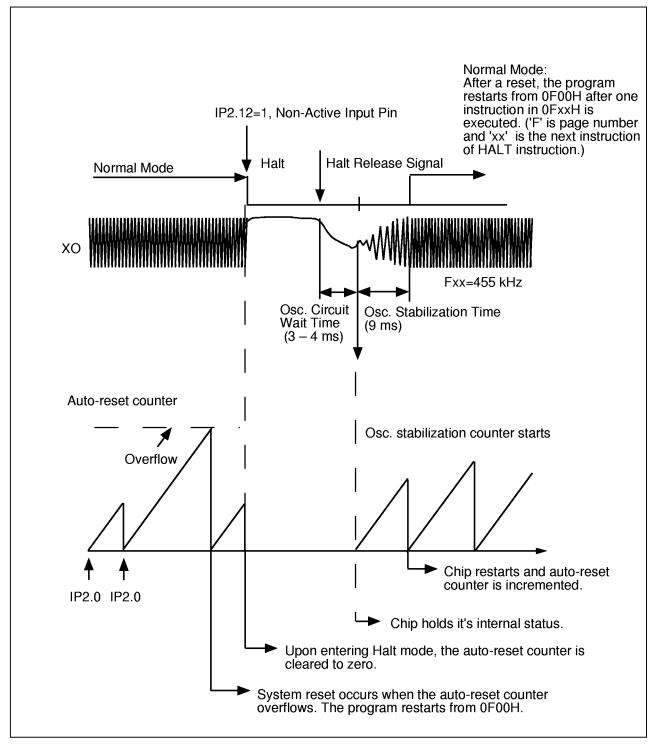

Figure 5-2. Auto-Reset Counter Function

## **Automatic Reset by Halt Mode Release**

This function resets the CPU by releasing Halt mode. The CPU is reset to its initial operating status and program execution starts from the reset address.

#### Halt Mode and Automatic Reset by Halt Release

Halt mode is used to reduce power consumption by stopping the oscillation and holding the internal state. Halt mode can be entered by forcing IP2.12 to high level (remaining input pins are non-active).

Before entering Halt mode, programmer should pre-set all key strobe output pins to active state even

though Halt mode causes some pins to remain active. For the 24 pins, P3.0–P3.3, P2.0, P2.2–2.4, and P2.5 are sent low and for 20 pins, P3.0–P3.3, P2.0, P2.2-P2.4 are sent low.

Forcing any key input port to active state causes the clock oscillation logic to start system initialization. At this time, the system is reset after the oscillation stabilization time elapses. A system reset causes program execution to start from address 0F00H.

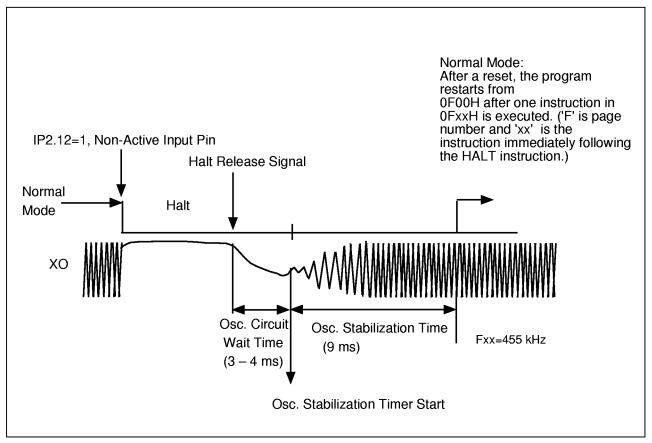

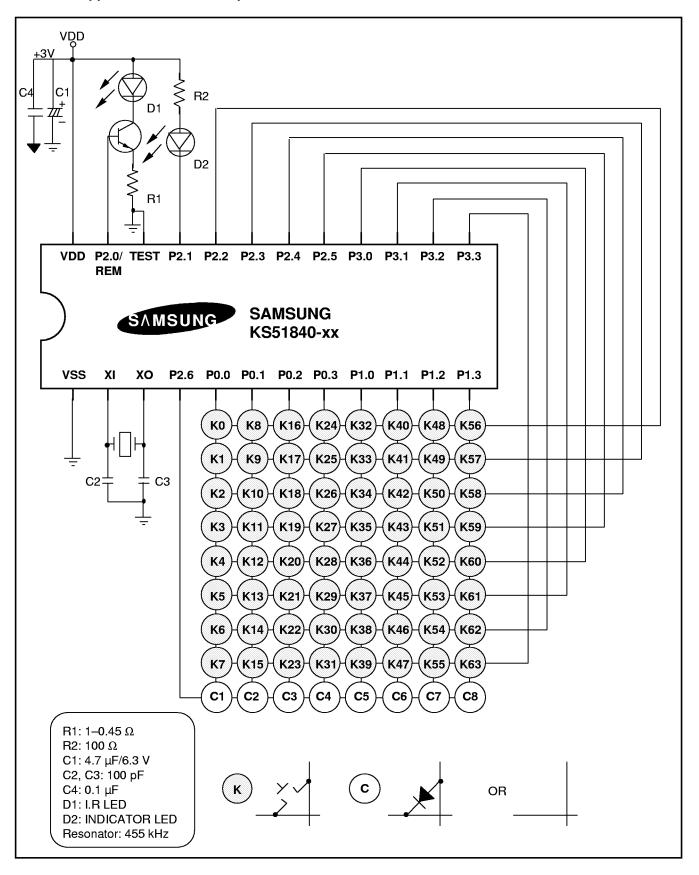

Figure 5-3. Reset Timing Diagram

## **KS51840 Application Circuit Example**

## **RESET and HALT Logic Diagram**

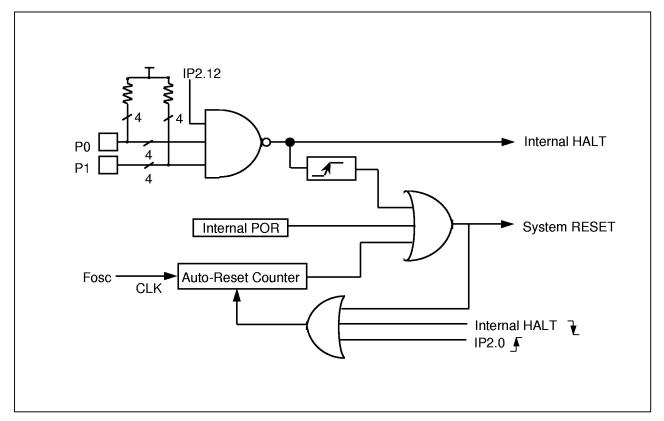

Figure 5-4. RESET and HALT Logic Diagram

## **HALT** mode programing

The KS51840/51845 can enter Halt mode by setting the IP2.12 pin to high level and forcing P0 and P1 input to a normal state. If IP2.12 is high and any input is active, the chip cannot enter Halt mode. Therefore, the next instruction is executed, which must be a clear command for IP2.12.

  timeb
          MOV
                    L,#0CH
                                ;No key pressed
          SETB
                     P2.(L)
                                ;Halt mode
```

;When no key is pressed, the chip enters Halt mode. Pressing any key while in Halt mode causes the chip to be initialized and restarted from the reset address.

;If any key is pressed between timea and timeb, the following instruction is executed.

MOV L,#0CH ;These two instructions remove the condition of re-entering Halt mode.

## **OUTPUT PIN DESCRIPTIONS**

\_\_\_\_

## **Indicator LED Drive Output**

To drive the indicator LED, the programmer should use P2.1 of the KS51840/51845 (which have higher current drive capability than other pins) in order to retain the pre-programmed status during Halt mode. Be careful to turn on the LED when a reset signal is generated. Because a reset signal sends all of the internal and external output pins to low level, the programmer must set LED output P2.1 to high state using a reset subroutine.

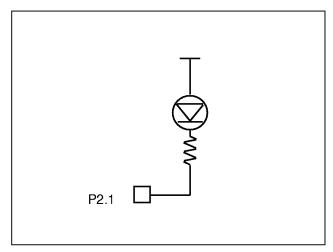

Figure5-5. LED Drive Output Circuit

## **Strobe Output Option**

To activate the optional strobe output function for TV and VCR remocon applications, the programmer must use the option selection strobe output pin (P2.6). This pin has lower current drive capability than other pins and retain the pre-programmed status while in Halt

This pin has lower current drive capability than other pins and retain the pre-programmed status while in Halt mode. Be careful to turn on the option strobe output pin when a reset signal is generated. Because the reset sends all internal and external output pins to low level, the option strobe output pin should always be non-active state (H-Z). The pin should be active only when you are checking option status to reduce current consumption.

Pin Usage	Key Output	LED Drive	Option Selection
P3.0-P3.3			
P2.2–P2.5	00	x	X
P2.1	0	00	0
P2.6	0	0	00

x :not allowed

o :good

oo :better

## **Output Pin Circuit Type**

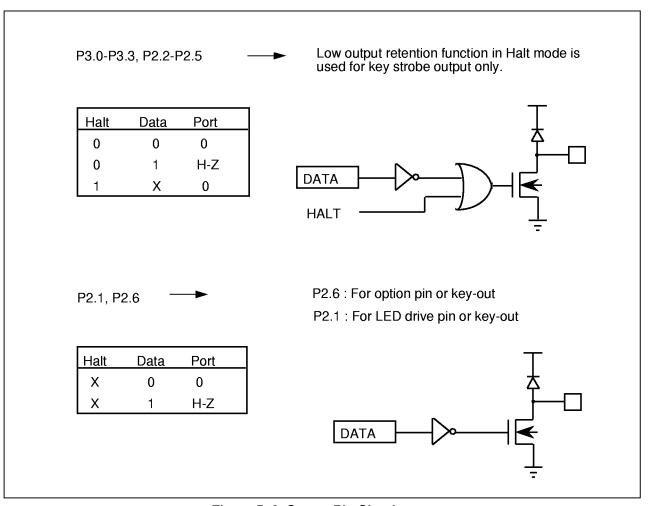

Figure 5-6. Output Pin Circuits

## **Soft Ware Delay Routine**

To obtain a constant time value, the KS51840/51845 use a software delay routine (there is not an internal timer interrupt). One instruction cycle is six oscillator clocks. Using a ceramic resonator with a constant frequency, you can calculate the time delay as follows:

t = 6 / Fxx x Number of Instructions

Where t: Elapsed time and Fxx: System clock.

## **Programming Tip**

To program a 1-ms delay:1 ms = 6/455 kHz x n, where Fxx = 455 kHz Therefore, n = 75.8 = 76 instructions

CLR	Α					
ADDS	A,#0BH	;Two instructions

;Total number of instructions for DLY1MS is 76.

#### NOTE

In order to lengthen the delay time, you can use an arithmetic instruction combination of L register and Accumulater. The L register causes the address lower pointer to access RAM space and the output port pointer to control the P2 (individual/serial output) port status.

- RAM manipulation instruction : RAM address pointer.
   MOV A,@HL CPNE @HL,A ADDS A,@HL SETB @HL.b
- P2 output control instruction: P2 pointer.
   SETB P2.(L) CLRB P2.(L)

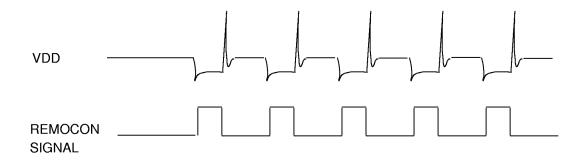

## **PROGRAMMING GUIDELINES**

When programming KS51840/51845 microcontroller, please follow the guidelines presented in this subsection.

## **PCB Artwork**

For remote control applications, turning the IR LED on and off may cause variations in transmission current ranging from a few hundred  $\mu A$  to a few hundred mA. This current variation generates overshoot and undershoot noise on the power line, causing a system malfunction.

To reduce noise and to stabilize the chip's operation, we recommend that the application designer reduce overshooting of the I.R. LED drive current and design PCB for the remote controller as follows: (The noise level should be limited to around 0.5 Vp-p, where Vp-p is the peak-to-peak voltage)

- Oscillation circuit should be located as near as possible to the chip.
- PCB pattern for VDD/VSS should be as wide and short as possible.
- I.R. LED drive TR and I.R. LED should be located as far as possible from the chip.
- Power supply battery and power capacitor should be located as near as possible to the chip.

## **SMDS**

When a breakpoint or single-step instruction is executed in area of PAGE and JP or CALL instruction, the JP or CALL may jump to the wrong address. We therefore recommend using a JPL or CALLL instruction (instead of PAGE and JP or PAGE and CALL) to avoid this problems. Note that JPL and CALLL are 2-byte instructions.

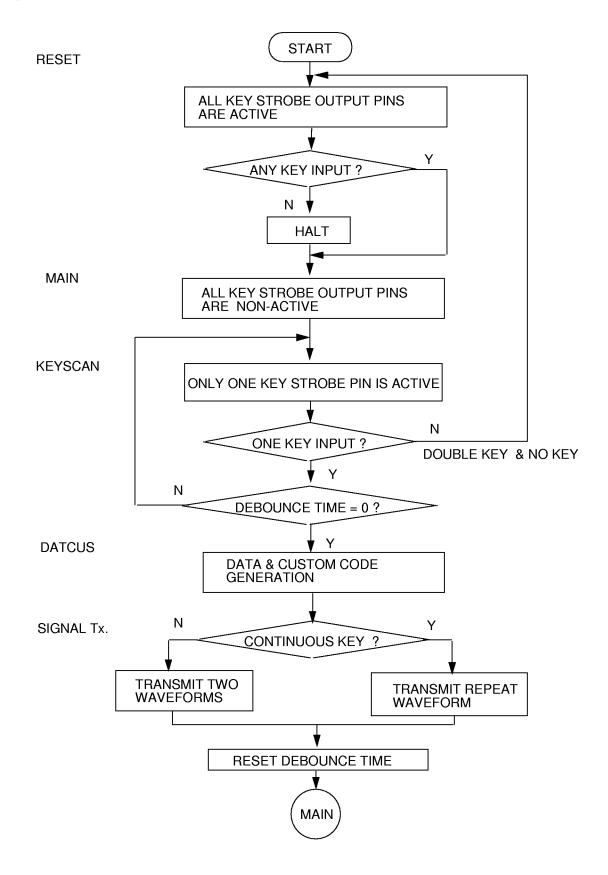

#### **Programming Guidelines for Reset Subroutine**

- 1. We recommend that you initialize a H register to either "0" or "4".
- 2. Do not write the instructions CALLL(PAGE + CALL) or JPL(PAGE + JP) to the reset address 0F00H. In other words, do not use a PAGE instruction at 0F00H.
- 3. Turn off the LED output pin.
- 4. To reduce current consumption, do not set the option output pin to active state.
- 5. Pre-set the remocon carrier frequency (to Fxx/12, Fxx/8, and so on) before remocon signal transmission.
- Because the program is initialized by an auto-reset or Halt mode release, even in normal operating state, do not pre-set all RAM data. If necessary, pre-set only the RAM area you need.
- 7. Be careful to control output pin status because some pins are automatically changed to active state.
- 8. To enter Halt mode, the internal port, IP2.12, should be set to high level and all of the input pins should be set to normal state.
- 9. To release Halt mode, an active level signal is supplied to input pins. If pulse width is less than 9 ms at Fxx=455 kHz, nothing happens and program re-enters Halt mode. That is, the external circuit should maintain the input pulse over a 9-ms interval in order to release Halt mode. After Halt mode is released, the hardware is reset. The hardware reset sends all internal and external output pins low and clears the stack to zero. However, H,L and A registers retain their previous status.
- If a rising edge is not generated at IP2.0, a reset signal occurs every 288 ms at Fxx=455 kHz. To prevent an auto-reset, IP2.0 should be forced low and then high at regular intervals (within 288 ms at Fxx=455 kHz).

## **Program Flowchart** (This program is only apply to KS51840)

#### **KS51840 KEYSCAN FUNCTION**

## Description

This program has an 8 x 9 key matrix, which consists of input P0 and P1 and output P2 and P3. Because pull-up resistors are connected, the normal state for all input pins is high level. The operating method for the keyscan function is as follows:

- All output pins remain active state (= low).
  If key is pressed, set all output pins to non-active state and rotate the pins to set only a pin to active state during debounce time.
- If key is pressed more than one or if no key is pressed, go to reset label. If a new key is pressed, reset debounce time, continuous flag, and key-in flag.

## **RAM Assignment**

H register selects #0

#### **KS51840 CODE GENERATION**

## **Description**

This program generates data code and custom code. The custom code is determined according to diodes between input ports and output pin (p2.6). The data code is as follows:

RAM -> DAT0 (D0-D3), DAT1 (D4-D7)

			/,					
	DO	D1	D2	DЗ	D4	D5	D6	D7
KEY0	0	0	0	0	0	0	0	0

## **RAM Assignment**

H register selects #4

CUS0: Custom code (c0 - c3)
CUS1: Custom code (c4 - c7)
CUS2: The complement of CUS0
CUS3: The complement of CUS1
DAT0: Data code (d0 - d3)

DATO: Data code (du - d3)

DAT1: Data code (d4 - d7)

: --> 32key: 00000010, 63key: 111111010

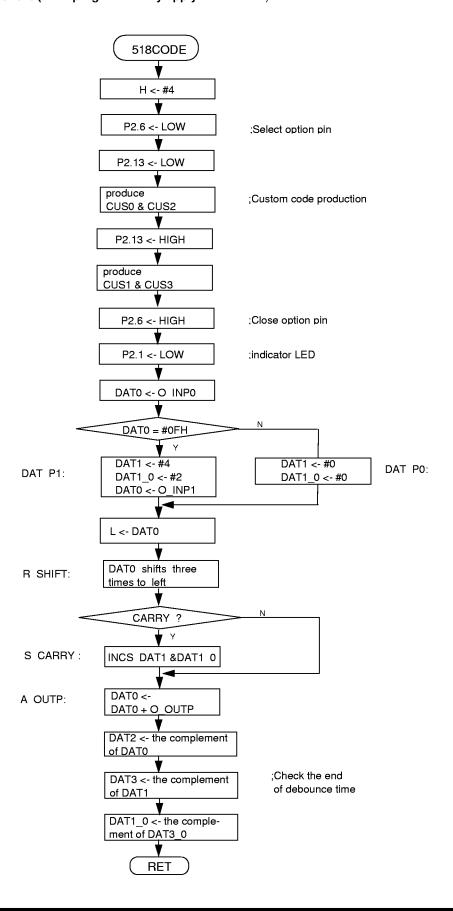

DAT2: The complement of DAT0
DAT3: The complement of DAT1

DAT1\_0: Data code (d4 - d7)

: --> 32key: 00000100, 63key: 111111100

DAT3\_0: The complement of DAT1\_0

#### **KS51840 SIGNAL TRANSMISSION**

#### Description

This program is for signal transmissions in SAMSUNG standard format. If one key is pressed, two frames are transmitted consecutively. The repeat pulse is transmitted until key-off. The frame interval is 60 ms. Each frame consists of leader code, custom code, and data code:

- Leader code ( high level for 4.5 ms and low level for 4.5 ms)
- 12-bit custom code
- 8-bit data code

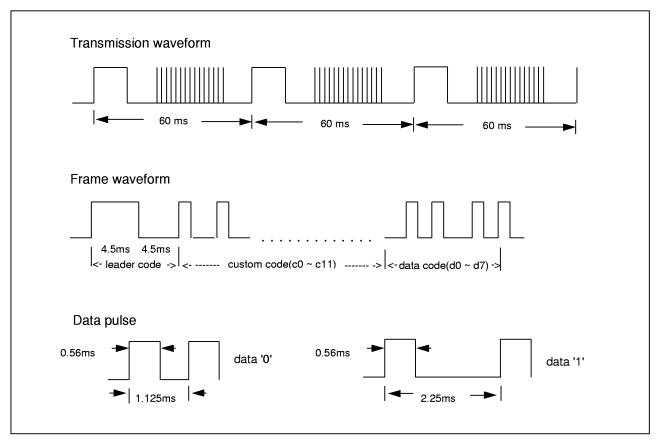

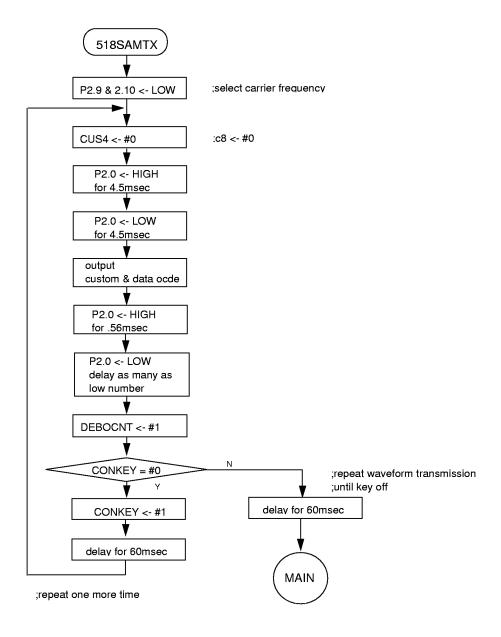

Figure 5-7. Transmission Waveforms

## **RAM Assignment**

This part is the same as for keyscan and code generation.
