Product Features

- 10 MHz to 140 MHz operating range
- Zero input-output propagation delay, adjustable by capacitive load on FBK input
- Multiple configurations, see "Available PI6C2308A Configurations" table
- Input to output delay, less than 150ps
- Multiple low skew outputs
  - Output-output skew less than 200ps
  - Device-device skew less than 500ps
  - Two banks of four outputs, Hi-Z by two select inputs
- Low Jitter, less than 200ps
- 3.3V operation
- Available in industrial &commercial temperatures
- Packages:
  - Space-saving 16-pin, 150-mil SOIC (W)
  - 16-pin TSSOP (L)

Functional Description

Providing two banks of four outputs, the PI6C2308A is a 3.3V zero-delay buffer designed to distribute clock signals in applications including PC, workstation, datacom, telecom, and high-performance systems. Each bank of four outputs can be controlled by the select inputs as shown in the Select Input Decoding Table.

The PI6C2308A provides 8 copies of a clock signal that has 150ps phase error compared to a reference clock. The skew between the output clock signals for PI6C2308A is less than 200ps. When there are no rising edges on the REF input, the PI6C2308A enters a power down state. In this mode, the PLL is off and all outputs are Hi-Z. This results in less than 12μA of current draw. The Select Input Decoding table shows additional examples when the PLL shuts down. The PI6C2308A configuration table shows all available devices.

The base part, PI6C2308A-1, provides output clocks in sync with a reference clock. With faster rise and fall times, the PI6C2308A-1H is the high-drive version of the PI6C2308A-1. Depending on which output drives the feedback pin, PI6C2308A-2 provides 2X and 1X clock signals on each output bank. The PI6C2308A-3 allows the user to obtain 4X and 2X frequencies on the outputs. The PI6C2308A-4 provides 2X clock signals on all outputs. PI6C2308A (-1, -2, -3, -4) allows bank B to be Hi-Z when all output clocks are not required. The PI6C2308A-6 allows bank B to switch from Reference clock to half of the frequency of Reference clock using the control inputs S1 and S2 if Bank A is connected to feedback FBK. In addition, using the control inputs S1 and S2, the PI6C2308A-6 allows bank A to switch from Reference clock to 2X the frequency of Reference clock if Bank B is connected to feedback FBK. For testing purposes, the select inputs connect the input clock directly to outputs.

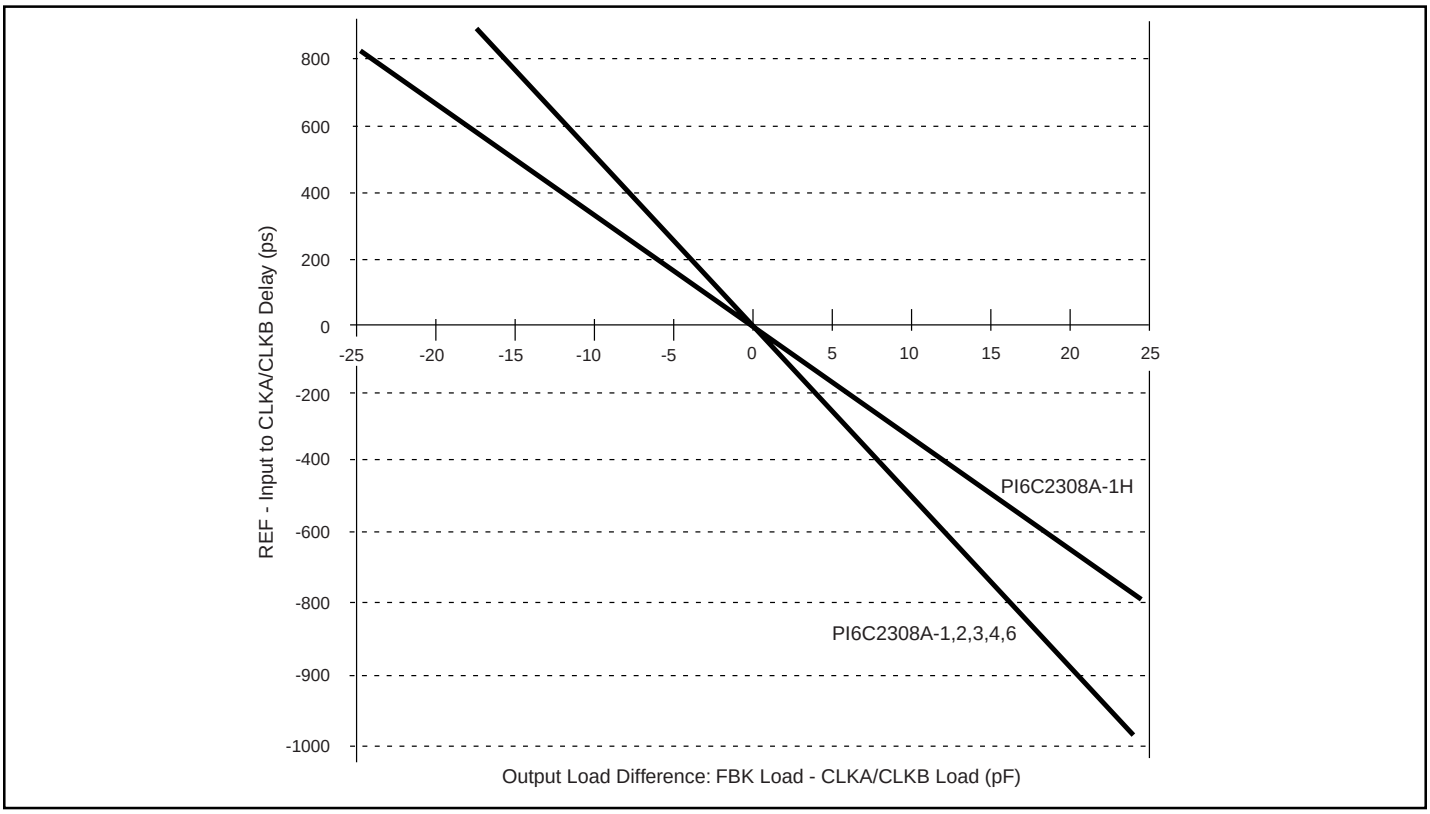
Zero Delay and Skew Control

REF. Input to CLKA/CLKB Delay vs. Difference in Loading between FBK pin and CLKA/CLKB pins



To close the feedback loop of the PI6C2308A, the FBK pin can be driven from any of the 8 available output pins. The output driving the FBK pin will be driving a total load of 7pF plus any additional load that it drives. The relative loading of this output (with respect to the remaining outputs) can adjust the input-output delay. This is shown in the graph above.

For applications requiring zero input-output delay, all outputs including the one providing feedback should be equally loaded. If input-output delay adjustments are required, use the above graph to calculate loading differences between the feedback output and remaining outputs.
