

NCP803

Very Low Supply Current 3-Pin Microprocessor Reset Monitor

The NCP803 is a cost-effective system supervisor circuit designed to monitor V_{CC} in digital systems and provide a reset signal to the host processor when necessary. No external components are required.

The reset output is driven active within 10 μ sec of V_{CC} falling through the reset voltage threshold. Reset is maintained active for a minimum of 140 msec after V_{CC} rises above the reset threshold. The NCP803 has an open drain active-low $\overline{\text{RESET}}$ output. The output of the NCP803 is guaranteed valid down to $V_{CC} = 1.0$ V and is available in a SOT-23 package.

The NCP803 is optimized to reject fast transient glitches on the V_{CC} line. Low supply current of 1.0 μ A ($V_{CC} = 3.2$ V) make this device suitable for battery powered applications.

Features

- Precision V_{CC} Monitor for 2.5 V, 3.0 V, 3.3 V, and 5.0 V Supplies
- Precision Monitoring Voltages from 1.6 V to 4.9 V Available in 100 mV Steps
- 140 msec Guaranteed Minimum $\overline{\text{RESET}}$ Output Duration
- $\overline{\text{RESET}}$ Output Guaranteed to $V_{CC} = 1.0$ V
- Low 1.0 μ A Supply Current
- V_{CC} Transient Immunity
- Small SOT-23 Package
- No External Components
- Wide Operating Temperature: -40°C to 105°C

Typical Applications

- Computers
- Embedded Systems
- Battery Powered Equipment
- Critical μ P Power Supply Monitoring

PIN DESCRIPTION

Pin No.	Symbol	Description
1	GND	Ground
2	$\overline{\text{RESET}}$	$\overline{\text{RESET}}$ output remains low while V_{CC} is below the reset voltage threshold, and for 240 msec (typ.) after V_{CC} rises above reset threshold.
3	V_{CC}	Supply Voltage: C = 100 nF is recommended as a bypass capacitor between V_{CC} and GND.

APPLICATIONS INFORMATION

V_{CC} Transient Rejection

The NCP803 provides accurate V_{CC} monitoring and reset timing during power-up, power-down, and brownout/sag conditions, and rejects negative-going transients (glitches) on the power supply line. Figure 2 shows the maximum transient duration vs. maximum negative excursion (overdrive) for glitch rejection. Any combination of duration and overdrive which lies **under** the curve will **not** generate a reset signal. Combinations above the curve are detected as a brownout or power-down. Typically, transient that goes 100 mV below the reset threshold and lasts 5 μs or less will not cause a reset pulse. Transient immunity can be improved by adding a capacitor in close proximity to the V_{CC} pin.

Figure 2. Maximum Transient Duration vs. Overdrive for Glitch Rejection at 25°C

Processors With Bidirectional I/O Pins

Some μP's (such as Motorola 68HC11) have bi-directional reset pins which interface easily with the Open Drain RESET output of the NCP803. As shown in Figure 3, one can connect directly to the RESET pin of the μP. The pull-up resistor avoids an undetermined voltage of the RESET pin.

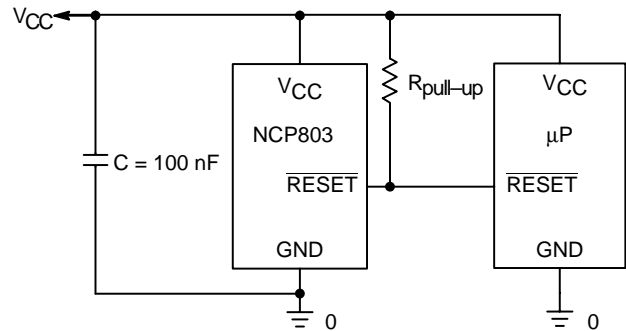

Figure 3. Interfacing to Bidirectional Reset I/O

NCP803 RESET Output Allows Use With Two Power Supplies

In numerous applications the pull-up resistor placed on the RESET output is connected to the supply voltage monitored by the IC. Nevertheless, a different supply voltage can also power this output and so level-shift from the monitored supply to reset the μP. However, if the NCP803's supply goes below 1 V, the RESET output ability to sink current will decrease and the result is a high state on the pin even though the supply's IC is under the threshold level. This occurs at a V_{CC} level that depends on the R_{pull-up} value and the voltage to which it is connected.
