

450MHz Differential Twisted-Pair Drivers

The EL5173 and EL5373 are single and triple high bandwidth amplifiers with a fixed gain of 2. They are primarily targeted for applications such as driving twisted-pair lines in component video applications. The inputs can be in either single-ended or differential form but the outputs are always in differential form.

The output common mode level for each channel is set by the associated REF pin, which have a -3dB bandwidth of over 190MHz. Generally, these pins are grounded but can be tied to any voltage reference.

All outputs are short circuit protected to withstand temporary overload condition.

The EL5173 and EL5373 are specified for operation over the full -40°C to +85°C temperature range.

TOP VIEW

EL5373
(24 LD QSOP)
TOP VIEW

Features

- Fully differential inputs and outputs
- Differential input range $\pm 2.3V$
- 450MHz 3dB bandwidth at fixed gain of 2
- 900V/ μs slew rate (EL5173)
- 1100V/ μs slew rate (EL5373)
- Single 5V or dual $\pm 5V$ supplies
- 40mA maximum output current
- Low power - 12mA per channel
- Pb-free plus anneal available (RoHS compliant)

Applications

- Twisted-pair drivers
- Differential line drivers
- VGA over twisted-pairs
- ADSL/HDSL drivers
- Single ended to differential amplification
- Transmission of analog signals in a noisy environment

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

EL5173, EL5373

Absolute Maximum Ratings ($T_A = 25^\circ\text{C}$)

Supply Voltage (V_{S+} to V_{S-}) 12.6V
 Supply Voltage Slew Rate 1V/ μs max.
 Maximum Output Current $\pm 60\text{mA}$
 Storage Temperature Range -65°C to $+150^\circ\text{C}$

Operating Junction Temperature $+135^\circ\text{C}$
 Recommended Operating Temperature -40°C to $+85^\circ\text{C}$
 Power Dissipation See Curves

CAUTION: Stresses above those listed in "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

IMPORTANT NOTE: All parameters having Min/Max specifications are guaranteed. Typ values are for information purposes only. Unless otherwise noted, all tests are at the specified temperature and are pulsed tests, therefore: $T_J = T_C = T_A$

Electrical Specifications $V_{S+} = +5\text{V}$, $V_{S-} = -5\text{V}$, $T_A = 25^\circ\text{C}$, $V_{IN} = 0\text{V}$, $R_{LD} = 200\Omega$, $C_{LD} = 1\text{pF}$, Unless Otherwise Specified

Description of Operation and Application Information

Product Description

The EL5173 and EL5373 are wide bandwidth, low power and single/differential ended to differential output amplifiers. They have a fixed gain of 2. The EL5173 is a single channel differential amplifier. The EL5373 is a triple channel differential amplifier. The EL5173 and EL5373 have a -3dB bandwidth of 450MHz while driving a 200Ω differential load. The EL5173 and EL5373 are available with a power down feature to reduce the power while the amplifiers are disabled.

Input, Output and Supply Voltage Range

The EL5173 and EL5373 have been designed to operate with a single supply voltage of 5V to 10V or a split supplies with its total voltage from 5V to 10V. The amplifiers have an input common mode voltage range from -4.5V to 3.4V for ±5V supply. The differential mode input range (DMIR) between the two inputs is from -2.3V to +2.3V. The input voltage range at the REF pin is from -3.3V to 3.7V. If the input common mode or differential mode signal is outside the above-specified ranges, it will cause the output signal distorted.

The output of the EL5173 and EL5373 can swing from -3.3V to 3.6V at 200Ω differential load at ±5V supply. As the load resistance becomes lower, the output swing is reduced.

Differential and Common Mode Gain Settings

As shown at the simplified schematic, since the feedback resistors RF and the gain resistor are integrated with 200Ω and 400Ω, the EL5173 and EL5373 have a fixed gain of 2. The common mode gain is always one.

Driving Capacitive Loads and Cables

The EL5173 and EL5373 can drive 16pF differential capacitor in parallel with 200Ω differential load with less than 3.5dB of peaking. If less peaking is desired in applications, a small series resistor (usually between 5Ω to 50Ω) can be placed in series with each output to eliminate most peaking. However, this will reduce the gain slightly.

When used as a cable driver, double termination is always recommended for reflection-free performance. For those applications, a back-termination series resistor at the amplifier's output will isolate the amplifier from the cable and allow extensive capacitive drive. However, other applications may have high capacitive loads without a back-termination resistor. Again, a small series resistor at the output can help to reduce peaking.

Disable/Power-Down

The EL5173 and EL5373 can be disabled and placed their outputs in a high impedance state. The turn off time is about 1.2μs and the turn on time is about 100ns. When disabled, the amplifier's supply current is reduced to 40μA for IS+ and 2.5μA for IS- typically, thereby effectively eliminating the power consumption. The amplifier's power down can be controlled by standard CMOS signal levels at the ENABLE pin. The applied logic signal is relative to VS+ pin. Letting the EN pin float or applying a signal that is less than 1.5V below VS+ will enable the amplifier. The amplifier will be disabled when the signal at EN pin is above VS+ -0.5V.

Output Drive Capability

The EL5173 and EL5373 have internal short circuit protection. Its typical short circuit current is ±55mA. If the output is shorted indefinitely, the power dissipation could easily increase such that the part will be destroyed.

Maximum reliability is maintained if the output current never exceeds $\pm 60\text{mA}$. This limit is set by the design of the internal metal interconnect.

Power Dissipation

With the high output drive capability of the EL5173 and EL5373 it is possible to exceed the 125°C absolute maximum junction temperature under certain load current conditions. Therefore, it is important to calculate the maximum junction temperature for the application to determine if the load conditions or package types need to be modified for the amplifier to remain in the safe operating area.

The maximum power dissipation allowed in a package is determined according to:

$$PD_{MAX} = \frac{T_{JMAX} - T_{AMAX}}{\theta_{JA}}$$

Where:

- T_{JMAX} = Maximum junction temperature
- T_{AMAX} = Maximum ambient temperature
- θ_{JA} = Thermal resistance of the package

The maximum power dissipation actually produced by an IC is the total quiescent supply current times the total power supply voltage, plus the power in the IC due to the load, or:

$$PD = i \times \left(V_S \times I_{SMAX} + V_S \times \frac{\Delta V_O}{R_{LD}} \right)$$

Where:

- V_S = Total supply voltage
- I_{SMAX} = Maximum quiescent supply current per channel
- ΔV_O = Maximum differential output voltage of the application
- R_{LD} = Differential load resistance
- I_{LOAD} = Load current
- i = Number of channels

By setting the two PD_{MAX} equations equal to each other, we can solve the output current and R_{LOAD} to avoid the device overheat.

Power Supply Bypassing and Printed Circuit Board Layout

As with any high frequency device, a good printed circuit board layout is necessary for optimum performance. Lead lengths should be as short as possible. The power supply pin must be well bypassed to reduce the risk of oscillation. For normal single supply operation, where the V_S- pin is connected to the ground plane, a single $4.7\mu\text{F}$ tantalum capacitor in parallel with a $0.1\mu\text{F}$ ceramic capacitor from V_{S+} to GND will suffice. This same capacitor combination should be placed at each supply pin to ground if split supplies are to be used. In this case, the V_S- pin becomes the negative supply rail.

For good AC performance, parasitic capacitance should be kept to minimum. Use of wire wound resistors should be avoided because of their additional series inductance. Use of sockets should also be avoided if possible. Sockets add parasitic inductance and capacitance that can result in compromised performance. Minimizing parasitic capacitance at the amplifier's inverting input pin is very important. The feedback resistor should be placed very close to the inverting input pin. Strip line design techniques are recommended for the signal traces.

Typical Applications
