

The TL494 is a fixed frequency, pulse width modulation control circuit designed primarily for Switchmode power supply control. This device features:

- Complete Pulse Width Modulation Control Circuitry
- On-Chip Oscillator With Master Or Slave Operation
- On-Chip Error Amplifiers
- On-Chip 5 Volt Reference
- Adjustable Dead-Time Control
- Uncommitted Output Transistors Rated to 500mA Source Or Sink
- Output Control For Push-Pull Or Single-Ended Operation
- Undervoltage Lockout

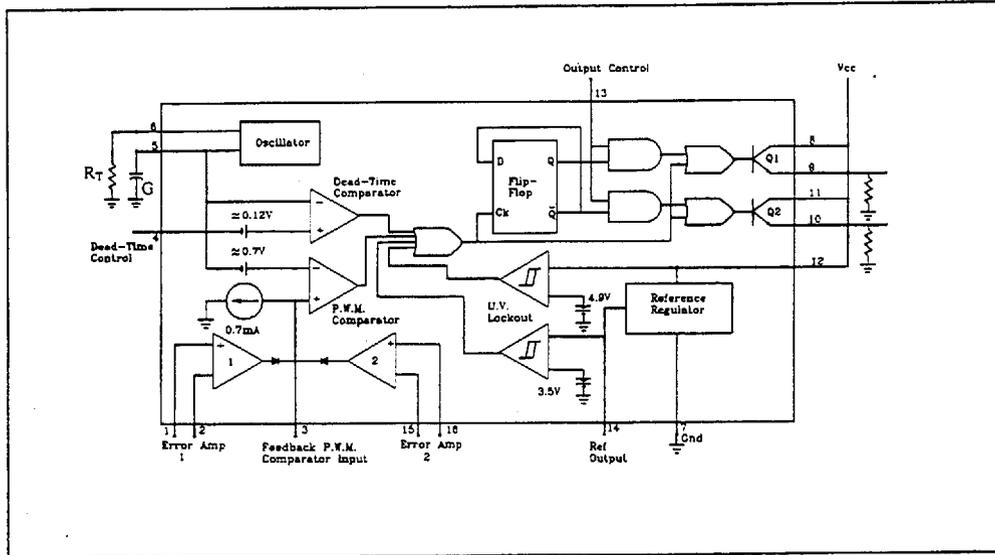

The TL494C is specified over the commercial operating range of 0°C to 70°C. The TL494I is specified over the industrial range of -25°C to 85°C.

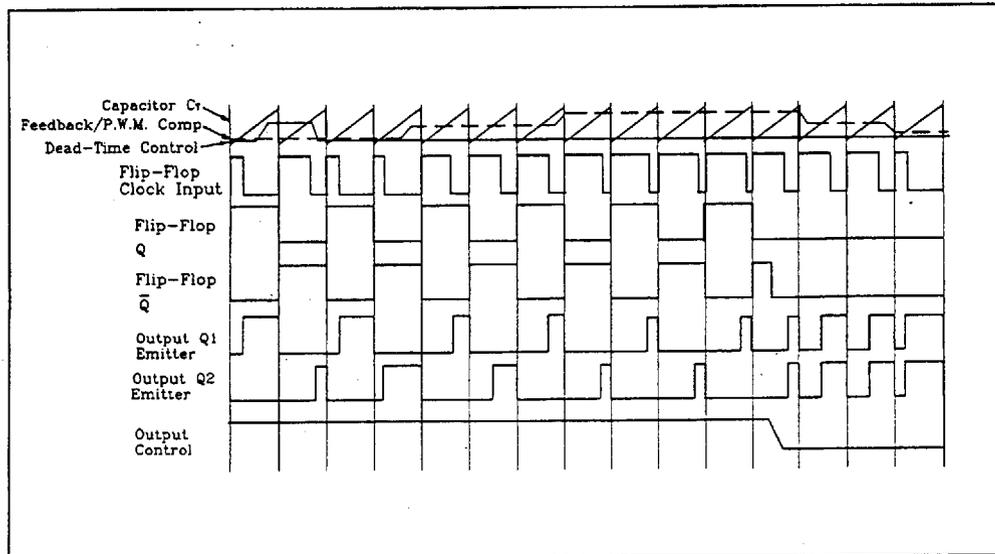

### ORDERING INFORMATION

Device	Temperature Range	Package
TL494CD	0°C to +70°C	Plastic DIP
TL494ID	-25°C to +85°C	Plastic DIP

### MAXIMUM RATINGS (Full operating ambient temperature range applies unless otherwise noted)

Rating	Symbol	TL494CD	TL494ID	Unit
Power Supply Voltage	$V_{CC}$	42	42	V
Collector Output Voltage	$V_{C1}, V_{C2}$	42	42	V
Collector Output Current (each transistor) (1)	$I_{C1}, I_{C2}$	500	500	mA
Amplifier Input Voltage Range	$V_R$	-0.3 to 42	-0.3 to 42	V
Power Dissipation @ $T_A \leq 45^\circ\text{C}$	$P_D$	1000	1000	mW
Operating Junction Temperature Plastic Package	$T_J$	125	125	$^\circ\text{C}$
Operating Ambient Temperature Range	$T_A$	0 to 70	-25 to 85	$^\circ\text{C}$
Storage Temperature Range Plastic Package	$T_{stg}$	-55 to 125	-55 to 125	$^\circ\text{C}$

NOTE 1: Maximum thermal limits must be observed.

### THERMAL CHARACTERISTICS

Characteristics	Symbol	16 DIP Plastic Package	Unit
Thermal Resistance, Junction to Ambient	$R_{\theta JA}$	80	$^\circ\text{C/W}$
Derating Ambient Temperature	$T_A$	45	$^\circ\text{C}$

### RECOMMENDED OPERATING CONDITIONS

Condition/Value	Symbol	TL494			Unit
		Min	Typ	Max	
Power Supply Voltage	$V_{CC}$	7.0	15	40	V
Collector Output Voltage	$V_{C1}, V_{C2}$	-	30	40	V
Collector Output Current (each transistor)	$I_{C1}, I_{C2}$	-	-	200	mA
Amplifier Input Voltage	$V_{in}$	-0.3	-	$V_{CC}-2.0$	V
Current Into Feedback Terminal	$I_F$	-	-	0.3	mA
Reference Output Current	$I_{ref}$	-	-	10	mA
Timing Resistor	$R_T$	1.8	30	500	$K\Omega$
Timing Capacitor	$C_T$	0.0047	0.001	10	$\mu\text{F}$
Oscillator Frequency	$f_{osc}$	1.0	40	200	KHz

### ELECTRICAL CHARACTERISTICS ( $V_{CC}=15\text{V}, C_T=0.01\mu\text{F}, R_T=12K\Omega$ unless otherwise noted.)

For typical values  $T_A = 25^\circ\text{C}$ , for min/max values  $T_A$  is operating ambient temperature range that applies unless otherwise noted.

## Description

The TL494 is a fixed-frequency pulse width modulation control circuit, incorporating the primary building blocks required for the control of a switching power supply. (See Figure 1.) An internal-linear sawtooth oscillator is frequency-programmable by two external components,  $R_T$  and  $C_T$ . The approximate oscillator frequency is determined by:

$$f_{osc} \approx \frac{1.1}{R_T \cdot C_T}$$

For more information refer to Figure 4.

Output pulse width modulation is accomplished by comparison of the positive sawtooth waveform across capacitor  $C_T$  to either of two control signals. The NOR gates, which drive output transistors Q1 and Q2, are enabled only when the flip-flop clock-input line is in its low state. This happens only during that portion of time when the sawtooth voltage is greater than the control signals. Therefore, an increase in control-signal amplitude causes a corresponding linear decrease of output pulse width. (Refer to the timing diagram shown in Figure 2.)

The control signals are external inputs that can be fed into the dead-time control, the error amplifier inputs, or the feedback input. The dead-time control comparator has an effective 120 mV input offset which limits the minimum output dead time to approximately the first 4% of the sawtooth-cycle time. This would result in a maximum duty cycle on a given output of 96% with the output control grounded, and 48% with it connected to the reference line. Additional dead time may be imposed on the output by setting the dead time-control input to a fixed voltage, ranging between 0 to 3.3V.

The pulse width modulator comparator provides a means for the error amplifiers to adjust the output pulse width from the maximum percent on-time, established by the dead time control input, down to zero, as the voltage at the feedback pin varies from 0.5 to 3.5V. Both error amplifiers have a common-mode input range from -0.3V to ( $V_{CC}-2V$ ), and may be used to sense power-supply output voltage and current. The error -amplifier outputs are active high and are ORed together at the non-inverting input of the pulse-width modulator comparator. With this configuration, the amplifier that demands minimum output on time, dominates control of the loop.

When capacitor  $C_T$  is discharged, a positive pulse is generated on the output of the dead-time comparator, which clocks the pulse-steering flip-flop and inhibits the output transistors, Q1 and Q2. With the output-control connected to the reference line, the pulse-steering flip-flop directs the modulated pulse to each of the two output transistors alternately for push-pull operation. The output frequency is equal to half that of the oscillator. Output drive can also be taken from Q1 or Q2, when single-ended operation with a maximum on-time of less than 50% is required. This is desirable when the output transformer has a ringback winding with a catch diode used for snubbing. When higher out-drive currents are required for single-ended operation, Q1 and Q2 may be connected in parallel, and the output-mode pin must be tied to ground to disable the flip-flop. The output frequency will now be equal to that of the oscillator.

The TL494 has an internal 5V reference capable of sourcing up to 10mA of load current for external bias circuits. The reference has an internal accuracy of  $\pm 1.5\%$  with a typical thermal drift of less than 50 mV over an operating range of 0 to 70 °C.

**FIGURE 3-FUNCTIONAL TABLE**

Input output Control	Output Function	$\frac{f_{out}}{f_{osc}} =$
Grounded	Single-ended P.W.M. at Q1 and Q2	1
