

KK74HC123A

Dual Retriggerable Monostable Multivibrator

The KK74HC123A is identical in pinout to the LS/ALS123. The device inputs are compatible with standard CMOS outputs; with pullup resistors, they are compatible with LS/ALSTTL outputs.

There are two trigger inputs, \overline{A} INPUT (negative edge) and B INPUT (positive edge). These inputs are valid for rising/falling signals.

The device may also be triggered by using the CLR input (positive-edge) because of the Schmitt-trigger input; after triggering the output maintains the MONOSTABLE state for the time period determined by the external resistor R_X and capacitor C_X . Taking CLR low breaks this MONOSTABLE STATE. If the next trigger pulse occurs during the MONOSTABLE period it makes the MONOSTABLE period longer.

- Outputs Directly Interface to CMOS, NMOS, and TTL
- Operating Voltage Range: 3.0 to 6.0 V
- Low Input Current: 1.0 μ A
- High Noise Immunity Characteristic of CMOS Devices

LOGIC DIAGRAM

PIN 16 = V_{CC}
 PIN 8 = GND

Note

- (1) C_X , R_X , D_X are external components.
- (2) D_X is a clamping diode.

The external capacitor is charged to V_{CC} in the stand-by state, i.e. no trigger. When the supply voltage is turned off C_X is discharged mainly through an internal parasitic diode. If C_X is sufficiently large and V_{CC} decreases rapidly, there will be some possibility of damaging the I.C. with a surge current or latch-up. If the voltage supply filter capacitor is large enough and V_{CC} decrease slowly, the surge current is automatically limited and damage the I.C. is avoided. The maximum forward current of the parasitic diode is approximately 20 mA.

** The In74HC123 will function at 2.0 V but for optimum pulse width stability, V_{CC} should be above 3.0 V.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{IN} and V_{OUT} should be constrained to the range $GND \leq (V_{IN} \text{ or } V_{OUT}) \leq V_{CC}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either GND or V_{CC}). Unused outputs must be left open.
