■ TYPICAL APPLICATION CIRCUIT

■ TYPICAL APPLICATION CIRCUIT

Application Circuit Using Differential Inputs

Note: 0.1µF ceramic capacitor must be placed much closely to the IC. For filtering lower frequency noise signals, a larger electrolytic capacitor of 10µF or greater should be placed as close as possible to the audio power amplifier.

■ APPLICATION INFORMATION

Shutdown Mode Operating

SHUTDOWN PIN INPUT	THE AMPLIFIER'S OUTPUT
LOW	MUTE(the current of this device will be reduced to 160μA)
HIGH	BTL
OTHERS	Don't Care

C_i(Input Capacitor)

The value of C_i is important to consider as it directly affects the bass performance of the application circuit. When C_i is required to allow the amplifier to bias the input signal to the proper dc level for optimum operation, it's value can be calculate by this equation:

$$C_i = 1 / (2\pi R_i F_c)$$

R_i:Input Impedance

F_c:High-pass Filter's Frequency

The low leakage tantalum or ceramic capacitors are suggested to be used as the input coupling capacitors, because of the small leakage current of the input ca-pacitors will cause the dc offset voltage at the input to the amplifier that reduces the operation headroom, especially at the high gain applications. It is important to let the positive side connecting to the higher dc level of the application when using the polarized capacitors.

Gain setting (VS GAIN0, GAIN1 and R_i)

Gain setting is determined by GAIN0 and GAIN1. The gains listed in the next table are realized by changing the taps on the input resistors inside the amplifier which will cause the internal input impedance(R_i) to be dependent on the gain setting as we can see listed in the next table.

A _v (dB)	GAIN0	GAIN1	R _i (kΩ)
6	0	0	90
10	0	1	70
15.6	1	0	45
21.6	1	1	25
