

Precision Analog Microcontroller, 12-Bit Analog I/O, Large Memory, ARM7TDMI MCU with Enhanced IRQ Handler

ADuC7124

FEATURES

Analog input/output

- Multichannel, 12-bit, 1 MSPS ADC
 - Up to 12 ADC channels
- Fully differential and single-ended modes
- 0 V to V_{REF} analog input range
- 12-bit voltage output DACs
 - 2 DAC outputs available
- On-chip voltage reference
- On-chip temperature sensor ($\pm 3^{\circ}\text{C}$)
- Voltage comparator

Microcontroller

- ARM7TDMI core, 16-bit/32-bit RISC architecture
- JTAG port supports code download and debug

Clocking options

- Trimmed on-chip oscillator ($\pm 3\%$)
- External watch crystal
- External clock source up to 41.78 MHz
- 41.78 MHz PLL with programmable divider

Memory

- 126 kB flash/EE memory, 32 kB SRAM
- In-circuit download, JTAG-based debug
- Software-triggered in-circuit reprogrammability

Vectored interrupt controller for FIQ and IRQ

- 8 priority levels for each interrupt type
- Interrupt on edge or level external pin inputs

On-chip peripherals

- 2× fully I²C compatible channels
- SPI (20 MBPS in master mode, 10 MBPS in slave mode)
 - With 4-byte FIFO on input and output stages
- 2× UART channels
 - With 16-byte FIFO on input and output stages
- Up to 30 GPIO port
 - All GPIOs are 5 V tolerant
- 4× general-purpose timers
 - Watchdog timer (WDT) and wake-up timer
- Programmable logic array (PLA)
 - 16 PLA elements
- 16-bit, 6-channel PWM
- Power supply monitor

Power

- Specified for 3 V operation
- Active mode: 11 mA at 5 MHz, 50 mA at 41.78 MHz

Packages and temperature range

- Fully specified for -40°C to $+125^{\circ}\text{C}$ operation
- 64-lead LFCSP

Tools

- Low cost QuickStart development system
- Full third-party support

APPLICATIONS

- Industrial control and automation systems
- Smart sensors, precision instrumentation
- Base station systems, optical networking
- Patient monitoring

REVISION HISTORY

7/10—Revision 0: Initial Version

GENERAL DESCRIPTION

The ADuC7124 is a fully integrated, 1 MSPS, 12-bit data acquisition system incorporating high performance multichannel ADCs, 16-bit/32-bit MCUs, and Flash/EE memory on a single chip.

The ADC consists of up to 12 single-ended inputs. An additional two inputs are available but are multiplexed with the two DAC output pins. The ADC can operate in single-ended or differential input mode. The ADC input voltage range is 0 V to V_{REF} . A low drift band gap reference, temperature sensor, and voltage comparator complete the ADC peripheral set.

The DAC output range is programmable to one of three voltage ranges. The DAC outputs have an enhanced feature of being able to retain their output voltage during a watchdog or software reset sequence.

The device operates from an on-chip oscillator and a PLL generating an internal high frequency clock of 41.78 MHz. This clock is routed through a programmable clock divider from which the MCU core clock operating frequency is generated. The microcontroller core is an ARM7TDMI[®], 16-bit/32-bit RISC machine, which offers up to 41 MIPS of peak performance. Thirty-two kilobytes of SRAM and 126 kB of nonvolatile Flash/EE memory are provided on-chip. The ARM7TDMI core views all memory and registers as a single linear array.

The ADuC7124 contains an advanced interrupt controller. The vectored interrupt controller (VIC) allows every interrupt to be assigned a priority level. It also supports nested interrupts to a maximum level of eight per IRQ and FIQ. When IRQ and FIQ interrupt sources are combined, a total of 16 nested interrupt levels are supported.

On-chip factory firmware supports in-circuit download via the UART serial interface port or the I²C port, while nonintrusive emulation is also supported via the JTAG interface. These features are incorporated into a low cost QuickStart™ development system supporting this MicroConverter® family.

The part contains a 16-bit PWM with six output signals.

For communication purposes, the part contains 2× I²C channels that can be individually configured for master or slave mode. An SPI interface supporting both master and slave modes is also provided. Thirdly, 2× UART channels are provided. Each UART contains a configurable 16-bit FIFO with receive and transmit buffers.

The part operates from 2.7 V to 3.6 V and is specified over an industrial temperature range of -40°C to +125°C. When operating at 41.78 MHz, the power dissipation is typically 120 mW. The ADuC7124 is available in a 64-lead LFCSP package.

HBM Passed Up To			3	kV	
FICDM Passed Up To			1.5	kV	

¹ All ADC channel specifications are guaranteed during normal core operation.

² Apply to all ADC input channels.

³ Measured using the factory-set default values in the ADC offset register (ADCOF) and gain coefficient register (ADCGN).

⁴ Not production tested but supported by design and/or characterization data on production release.

⁵ Measured using the factory-set default values in ADCOF and ADCGN with an external AD845 op amp as an input buffer stage as shown in Figure 36. Based on external ADC system components, the user may need to execute a system calibration to remove external endpoint errors and achieve these specifications (see the Calibration section).

⁶ The input signal can be centered on any dc common-mode voltage (V_{CM}) as long as this value is within the ADC voltage input range specified.

⁷ DAC linearity is calculated using a reduced code range of 100 to 3995.

⁸ DAC gain error is calculated using a reduced code range of 100 to internal $2.5 V_{REF}$.

⁹ Endurance is qualified as per JEDEC Standard 22 Method A117 and measured at -40°C , $+25^\circ\text{C}$, $+85^\circ\text{C}$, and $+125^\circ\text{C}$.

¹⁰ Retention lifetime equivalent at junction temperature (T_J) = 85°C as per JEDEC Standard 22 Method A117. Retention lifetime derates with junction temperature.

¹¹ Test carried out with a maximum of eight I/Os set to a low output level.

¹² Power supply current consumption is measured in normal, pause, and sleep modes under the following conditions: normal mode with 3.6 V supply, pause mode with 3.6 V supply, and sleep mode with 3.6 V supply.

¹³ IOV_{DD} power supply current increases typically by 2 mA during a Flash/EE erase cycle.

¹⁴ This current must be added to the AV_{DD} current.

TIMING SPECIFICATIONS

I²C Timing

Table 2. I²C Timing in Fast Mode (400 kHz)

Parameter	Description	Slave		Master	Unit
		Min	Max	Typ	
t _L	SCLK low pulse width	200		1360	ns
t _H	SCLK high pulse width	100		1140	ns
t _{SHD}	Start condition hold time	300			ns
t _{DSU}	Data setup time	100		740	ns
t _{DHD}	Data hold time	0		400	ns
t _{RSU}	Setup time for repeated start	100			ns
t _{PSU}	Stop condition setup time	100		800	ns
t _{BUF}	Bus-free time between a stop condition and a start condition	1.3			μs

ABSOLUTE MAXIMUM RATINGS

AGND = REFGND = DACGND = GND_{REF}, T_A = 25°C, unless otherwise noted.

Table 8.

Parameter	Rating
AV _{DD} to IOV _{DD}	−0.3 V to +0.3 V
AGND to DGND	−0.3 V to +0.3 V
IOV _{DD} to IOGND, AV _{DD} to AGND	−0.3 V to +6 V
Digital Input Voltage to IOGND	−0.3 V to +5.3 V
Digital Output Voltage to IOGND	−0.3 V to IOV _{DD} + 0.3 V
V _{REF} to AGND	−0.3 V to AV _{DD} + 0.3 V
Analog Inputs to AGND	−0.3 V to AV _{DD} + 0.3 V
Analog Outputs to AGND	−0.3 V to AV _{DD} + 0.3 V
Operating Temperature Range, Industrial	−40°C to +125°C
Storage Temperature Range	−65°C to +150°C
Junction Temperature	150°C
θ _{JA} Thermal Impedance	
64-Lead LFCSP	24°C/W
Peak Solder Reflow Temperature	
SnPb Assemblies (10 sec to 30 sec)	240°C
RoHS Compliant Assemblies (20 sec to 40 sec)	260°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

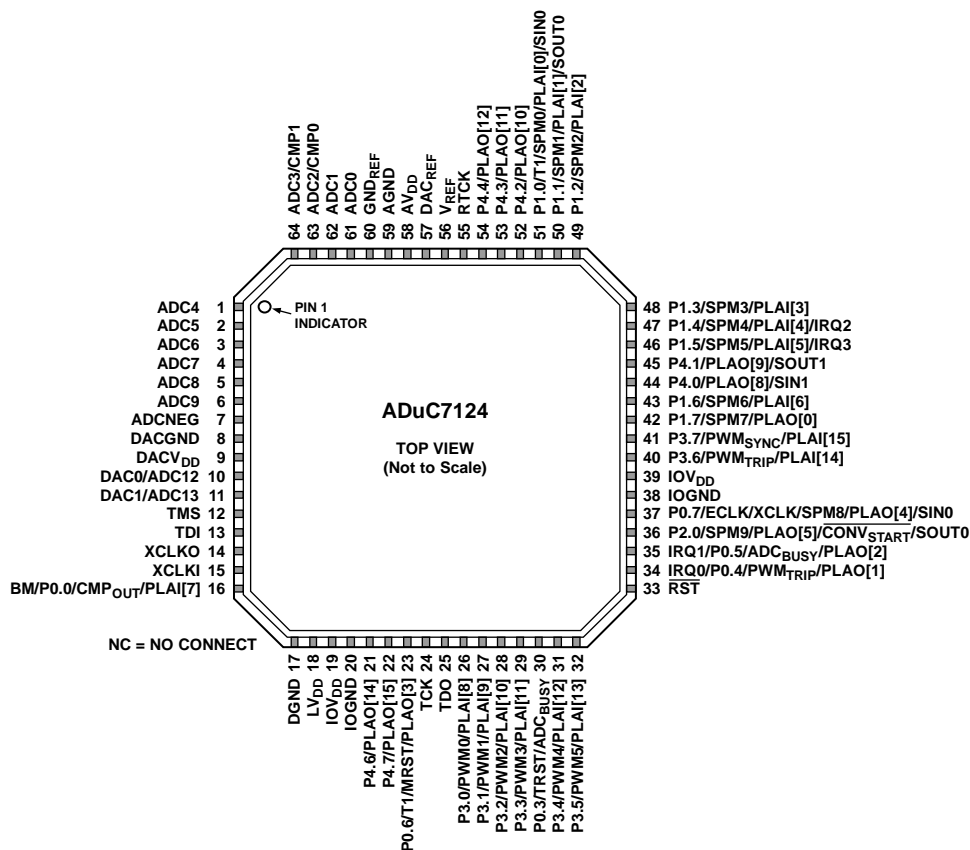

Only one absolute maximum rating can be applied at any one time.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

NOTES
1. THE EXPOSED PADDLE MUST BE SOLDERED TO THE PCB GROUND TO ENSURE PROPER HEAT DISSIPATION, NOISE, AND MECHANICAL STRENGTH BENEFITS.

09123-107

Figure 7. Pin Configuration

Table 9. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	ADC4	Single-Ended or Differential Analog Input 4.
2	ADC5	Single-Ended or Differential Analog Input 5.
3	ADC6	Single-Ended or Differential Analog Input 6.
4	ADC7	Single-Ended or Differential Analog Input 7.
5	ADC8	Single-Ended or Differential Analog Input 8.
6	ADC9	Single-Ended or Differential Analog Input 9.
7	ADCNEG	Bias Point or Negative Analog Input of the ADC in Pseudo Differential Mode. Must be connected to the ground of the signal to convert. This bias point must be between 0 V and 1 V.
8	DACGND	Ground for the DAC. Typically connected to AGND.
9	DACV _{DD}	3.3 V Power Supply for the DACs. Must be connected to AV _{DD} .
10	DAC0/ADC12	DAC0 Voltage Output/Single-Ended or Differential Analog Input 12.
11	DAC1/ADC13	DAC1 Voltage Output/Single-Ended or Differential Analog Input 13.
12	TMS	JTAG Test Port Input, Test Mode Select. Debug and download access.
13	TDI	JTAG Test Port Input, Test Data In.
14	XCLKO	Output from the Crystal Oscillator Inverter.
15	XCLKI	Input to the Crystal Oscillator Inverter and Input to the Internal Clock Generator Circuits.

ADuC7124

Pin No.	Mnemonic	Description
16	BM/P0.0/CMP _{OUT} /PLAI[7]	Multifunction I/O Pin. Boot mode. The ADuC7124 enters download mode if BM is low at reset and executes code if BM is pulled high at reset through a 1 kΩ resistor. General-Purpose Input and Output Port 0.0/Voltage Comparator Output/Programmable Logic Array Input Element 7.
17	DGND	Ground for Core Logic.
18	LV _{DD}	2.6 V Output of the On-Chip Voltage Regulator. This output must be connected to a 0.47 μF capacitor to DGND only.
19	IOV _{DD}	3.3 V Supply for GPIO and Input of the On-Chip Voltage Regulator.
20	IOGND	Ground for GPIO. Typically connected to DGND.
21	P4.6/PLAO[14]	General-Purpose Input and Output Port 4.6/Programmable Logic Array Output Element 14.
22	P4.7/PLAO[15]	General-Purpose Input and Output Port 4.7/Programmable Logic Array Output Element 15.
23	P0.6/T1/MRST/PLAO[3]	Multifunction Pin, Driven Low After Reset. General-Purpose Output Port 0.6/Timer1 Input/Power-On Reset Output/Programmable Logic Array Output Element 3.
24	TCK	JTAG Test Port Input, Test Clock. Debug and download access.
25	TDO	JTAG Test Port Output, Test Data Out.
26	P3.0/PWM0/PLAI[8]	General-Purpose Input and Output Port 3.0/PWM Phase 0/Output/Programmable Logic Array Input Element 8.

TERMINOLOGY

ADC SPECIFICATIONS

Integral Nonlinearity (INL)

The maximum deviation of any code from a straight line passing through the endpoints of the ADC transfer function. The endpoints of the transfer function are zero scale, a point $\frac{1}{2}$ LSB below the first code transition, and full scale, a point $\frac{1}{2}$ LSB above the last code transition.

Differential Nonlinearity (DNL)

The difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

Offset Error

The deviation of the first code transition (0000 . . . 000) to (0000 . . . 001) from the ideal, that is, $+\frac{1}{2}$ LSB.

Gain Error

The deviation of the last code transition from the ideal AIN voltage (full scale – 1.5 LSB) after the offset error has been adjusted out.

Signal to (Noise + Distortion) Ratio

The measured ratio of signal to (noise + distortion) at the output of the ADC. The signal is the rms amplitude of the fundamental. Noise is the rms sum of all nonfundamental signals up to half the sampling frequency ($f_s/2$), excluding dc.

The ratio is dependent upon the number of quantization levels in the digitization process; the more levels, the smaller the quantization noise.

The theoretical signal to (noise + distortion) ratio for an ideal N-bit converter with a sine wave input is given by

$$\text{Signal to (Noise + Distortion)} = (6.02 N + 1.76) \text{ dB}$$

Thus, for a 12-bit converter, this is 74 dB.

Total Harmonic Distortion

The ratio of the rms sum of the harmonics to the fundamental.

DAC SPECIFICATIONS

Relative Accuracy

Otherwise known as endpoint linearity, relative accuracy is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for zero error and full-scale error.

Voltage Output Settling Time

The amount of time it takes the output to settle to within a 1 LSB level for a full-scale input change.

OVERVIEW OF THE ARM7TDMI CORE

The ARM7[®] core is a 32-bit reduced instruction set computer (RISC). It uses a single 32-bit bus for instruction and data. The length of the data can be eight bits, 16 bits, or 32 bits. The length of the instruction word is 32 bits.

The ARM7TDMI is an ARM7 core with four additional features.

- T support for the Thumb[®] (16-bit) instruction set.
- D support for debug.
- M support for long multiplications.
- I includes the EmbeddedICE module to support embedded system debugging.

THUMB MODE (T)

An ARM instruction is 32 bits long. The ARM7TDMI processor supports a second instruction set that has been compressed into 16 bits, called the Thumb instruction set. Faster execution from 16-bit memory and greater code density can usually be achieved by using the Thumb instruction set instead of the ARM instruction set, which makes the ARM7TDMI core particularly suitable for embedded applications.

However, the Thumb mode has two limitations:

- Thumb code typically requires more instructions for the same job. As a result, ARM code is usually best for maximizing the performance of time-critical code.
- The Thumb instruction set does not include some of the instructions needed for exception handling, which automatically switches the core to ARM code for exception handling.

See the ARM7TDMI user guide for details on the core architecture, the programming model, and both the ARM and ARM Thumb instruction sets.

LONG MULTIPLY (M)

The ARM7TDMI instruction set includes four extra instructions that perform 32-bit by 32-bit multiplication with a 64-bit result and 32-bit by 32-bit multiplication-accumulation (MAC) with a 64-bit result. These results are achieved in fewer cycles than required on a standard ARM7 core.

EmbeddedICE (I)

EmbeddedICE provides integrated on-chip support for the core. The EmbeddedICE module contains the breakpoint and watchpoint registers that allow code to be halted for debugging purposes. These registers are controlled through the JTAG test port.

When a breakpoint or watchpoint is encountered, the processor halts and enters debug state. Once in a debug state, the processor registers can be inspected as well as the Flash/EE, SRAM, and memory mapped registers.

EXCEPTIONS

ARM supports five types of exceptions and a privileged processing mode for each type. The five types of exceptions are

- Normal interrupt or IRQ. This is provided to service general-purpose interrupt handling of internal and external events.
- Fast interrupt or FIQ. This is provided to service data transfers or communication channels with low latency. FIQ has priority over IRQ.
- Memory abort.
- Attempted execution of an undefined instruction.
- Software interrupt instruction (SWI). This can be used to make a call to an operating system.

Typically, the programmer defines interrupt as IRQ, but for higher priority interrupt, that is, faster response time, the programmer can define interrupt as FIQ.

ARM REGISTERS

ARM7TDMI has a total of 37 registers: 31 general-purpose registers and six status registers. Each operating mode has dedicated banked registers.

When writing user-level programs, 15 general-purpose 32-bit registers (R0 to R14), the program counter (R15), and the current program status register (CPSR) are usable. The remaining registers are only used for system-level programming and exception handling.

When an exception occurs, some of the standard registers are replaced with registers specific to the exception mode. All exception modes have replacement banked registers for the stack pointer (R13) and the link register (R14), as represented in Figure 22. The fast interrupt mode has more registers (R8 to R12) for fast interrupt processing. This means that the interrupt processing can begin without the need to save or restore these registers, and therefore, save critical time in the interrupt handling process.

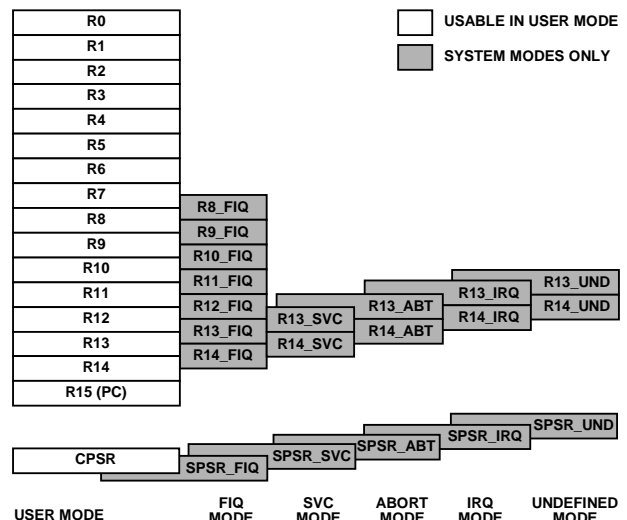

Figure 22. Register Organization

More information relative to the model of the programmer and the ARM7TDMI core architecture can be found in the following materials from ARM:

- DDI0029G, *ARM7TDMI Technical Reference Manual*
- DDI-0100, *ARM Architecture Reference Manual*

INTERRUPT LATENCY

The worst-case latency for a fast interrupt request (FIQ) consists of the following:

- The longest time the request can take to pass through the synchronizer
- The time for the longest instruction to complete (the longest instruction is an LDM) that loads all the registers including the PC
- The time for the data abort entry
- The time for the FIQ entry

At the end of this time, the ARM7TDMI executes the instruction at 0x1C (FIQ interrupt vector address). The maximum total time is 50 processor cycles, which is just under 1.2 μ s in a system using a continuous 41.78 MHz processor clock.

The maximum interrupt request (IRQ) latency calculation is similar but must allow for the fact that FIQ has higher priority and could delay entry into the IRQ handling routine for an arbitrary length of time. This time can be reduced to 42 cycles if the LDM command is not used. Some compilers have an option to compile without using this command. Another option is to run the part in Thumb mode where the time is reduced to 22 cycles.

The minimum latency for FIQ or IRQ interrupts is a total of five cycles, which consist of the shortest time the request can take through the synchronizer plus the time to enter the exception mode.

Note that the ARM7TDMI always runs in ARM (32-bit) mode when in privileged modes, for example, when executing interrupt service routines.

MEMORY ORGANIZATION

The ADuC7124 incorporates three separate blocks of memory: 32 kB of SRAM and two 64 kB blocks of on-chip Flash/EE memory. There are 126 kB of on-chip Flash/EE memory available to the user, and the remaining 2 kB are reserved for the system kernel. These blocks are mapped as shown in Figure 23.

Note that, by default, after a reset, the Flash/EE memory is mirrored at Address 0x00000000. It is possible to remap the SRAM at Address 0x00000000 by clearing Bit 0 of the REMAP MMR. This remap function is described in more detail in the Flash/EE memory chapter.

Figure 23. Physical Memory Map

MEMORY ACCESS

The ARM7 core sees memory as a linear array of a 2^{32} byte location where the different blocks of memory are mapped as outlined in Figure 23.

The ADuC7124 memory organization is configured in little endian format: the least significant byte is located in the lowest byte address and the most significant byte in the highest byte address.

Figure 24. Little Endian Format

FLASH/EE MEMORY

The 128 kB of Flash/EE are organized as two banks of $32 \text{ kB} \times 16 \text{ bits}$. In the first block, $31 \text{ kB} \times 16 \text{ bits}$ is user space and $1 \text{ kB} \times 16 \text{ bits}$ is reserved for the factory-configured boot page. The page size of this Flash/EE memory is 512 bytes.

The second 64 kB block is organized in a similar manner. It is arranged in $32 \text{ kB} \times 16 \text{ bits}$. All of this is available as user space.

The 126 kB of Flash/EE are available to the user as code and non volatile data memory. There is no distinction between data and program because ARM code shares the same space. The real width of the Flash/EE memory is 16 bits, meaning that, in ARM mode (32-bit instruction), two accesses to the Flash/EE are necessary for each instruction fetch. Therefore, it is recommended that Thumb mode be used when executing from Flash/EE memory for optimum access speed. The maximum access speed for the Flash/EE memory is 41.78 MHz in Thumb mode and 20.89 MHz in full ARM mode (see the Execution Time from SRAM and Flash/EE section).

SRAM

The 32 kB of SRAM are available to the user, organized as $8 \text{ kB} \times 32 \text{ bits}$, that is, 16 kB words. ARM code can run directly from SRAM at 41.78 MHz, given that the SRAM array is configured as a 32-bit wide memory array (see the Execution Time from SRAM and Flash/EE section).

MEMORY MAPPED REGISTERS

The memory mapped register (MMR) space is mapped into the upper two pages of the memory array and accessed by indirect addressing through the ARM7 banked registers.

The MMR space provides an interface between the CPU and all on-chip peripherals. All registers except the core registers reside in the MMR area. All shaded locations shown in Figure 25 are unoccupied or reserved locations and should not be accessed by user software. Table 28 shows a full MMR memory map.

The access time reading or writing a MMR depends on the advanced microcontroller bus architecture (AMBA) bus used to access the peripheral. The processor has two AMBA buses: the advanced high performance bus (AHB) used for system modules, and the advanced peripheral bus (APB) used for the lower performance peripheral. Access to the AHB is one cycle, and access to the APB is two cycles. All peripherals on the ADuC7124 are on the APB except the Flash/EE memory and the GPIOs.

ADC CIRCUIT OVERVIEW

The analog-to-digital converter (ADC) incorporates a fast, multichannel, 12-bit ADC. It can operate from 2.7 V to 3.6 V supplies and is capable of providing a throughput of up to 1 MSPS when the clock source is 41.78 MHz. This block provides the user with a multichannel multiplexer, a differential track-and-hold, an on-chip reference, and an ADC.

The ADC consists of a 12-bit successive approximation converter based around two capacitor DACs. Depending on the input signal configuration, the ADC can operate in one of three different modes.

- Fully differential mode, for small and balanced signals
- Single-ended mode, for any single-ended signals
- Pseudo differential mode, for any single-ended signals, taking advantage of the common-mode rejection offered by the pseudo differential input

The converter accepts an analog input range of 0 V to V_{REF} when operating in single-ended or pseudo differential mode. In fully differential mode, the input signal must be balanced around a common-mode voltage (V_{CM}) in the 0 V to AV_{DD} range with a maximum amplitude of $2 \times V_{REF}$ (see Figure 26).

Figure 26. Examples of Balanced Signals in Fully Differential Mode

A high precision, low drift, factory calibrated, 2.5 V reference is provided on chip. An external reference can also be connected as described in the Band Gap Reference section.

Single or continuous conversion modes can be initiated in the software. An external $CONV_{START}$ pin, an output generated from the on-chip PLA, or a Timer0 or Timer1 overflow can also be used to generate a repetitive trigger for ADC conversions.

A voltage output from an on-chip band gap reference proportional to absolute temperature can also be routed through the front-end ADC multiplexer, effectively an additional ADC channel input. This facilitates an internal temperature sensor channel that measures die temperature.

TRANSFER FUNCTION

Pseudo Differential and Single-Ended Modes

In pseudo differential or single-ended mode, the input range is 0 V to V_{REF} . The output coding is straight binary in pseudo differential and single-ended modes with

$$1 \text{ LSB} = FS/4096, \text{ or}$$

$$2.5 \text{ V}/4096 = 0.61 \text{ mV, or}$$

$$610 \mu\text{V when } V_{REF} = 2.5 \text{ V}$$

The ideal code transitions occur midway between successive integer LSB values (that is, $\frac{1}{2}$ LSB, $\frac{3}{2}$ LSB, $\frac{5}{2}$ LSB, ..., $FS - \frac{3}{2}$ LSB). The ideal input/output transfer characteristic is shown in Figure 27.

Figure 27. ADC Transfer Function in Pseudo Differential or Single-Ended Mode

Fully Differential Mode

The amplitude of the differential signal is the difference between the signals applied to the V_{IN+} and V_{IN-} pins (that is, $V_{IN+} - V_{IN-}$). V_{IN+} is selected by the ADCCP register, and V_{IN-} is selected by the ADCCN register. The maximum amplitude of the differential signal is, therefore, $-V_{REF}$ to $+V_{REF}$ p-p (that is, $2 \times V_{REF}$). This is regardless of the common mode (CM). The common mode is the average of the two signals, for example, $(V_{IN+} + V_{IN-})/2$, and is, therefore, the voltage that the two inputs are centered on. This results in the span of each input being $CM \pm V_{REF}/2$. This voltage has to be set up externally, and its range varies with V_{REF} (see the Driving the Analog Inputs section).

The output coding is twos complement in fully differential mode with $1 \text{ LSB} = 2 \times V_{REF}/4096$, or $2 \times 2.5 \text{ V}/4096 = 1.22 \text{ mV}$ when $V_{REF} = 2.5 \text{ V}$. The output result is ± 11 bits, but this is shifted by one to the right. This allows the result in ADCDAT to be declared as a signed integer when writing C code. The designed code transitions occur midway between successive integer LSB values (that is, $\frac{1}{2}$ LSB, $\frac{3}{2}$ LSB, $\frac{5}{2}$ LSB, ..., $FS - \frac{3}{2}$ LSB). The ideal input/output transfer characteristic is shown in Figure 28.

Figure 28. ADC Transfer Function in Differential Mode

TYPICAL OPERATION

Once configured via the ADC control and channel selection registers, the ADC converts the analog input and provides a 12-bit result in the ADC data register.

The top four bits are the sign bits. The 12-bit result is placed in Bit 16 to Bit 27 as shown in Figure 29. Again, it should be noted that in fully differential mode, the result is represented in twos complement format. In pseudo differential and single-ended modes, the result is represented in straight binary format.

Figure 29. ADC Result Format

The same format is used in DACxDAT, simplifying the software.

Current Consumption

The ADC in standby mode, that is, powered up but not converting, typically consumes 640 μ A. The internal reference adds 140 μ A. During conversion, the extra current is 0.3 μ A multiplied by the sampling frequency (in kHz).

Timing

Figure 30 gives details of the ADC timing. The user controls the ADC clock speed and the number of acquisition clocks in the ADCCON MMR. By default, the acquisition time is eight clocks, and the clock divider is two. The number of extra clocks (such as bit trial or write) is set to 19, which gives a sampling rate of 774 kSPS. For conversion on temperature sensor, the ADC acquisition time is automatically set to 16 clocks, and the ADC clock divider is set to 32. When using multiple channels including the temperature sensor, the timing settings revert to the user-defined settings after reading the temperature sensor channel.

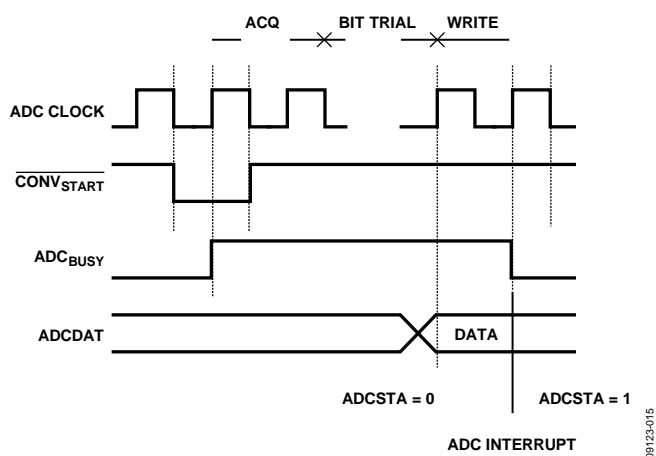

Figure 30. ADC Timing

MMRS INTERFACE

The ADC is controlled and configured via the eight MMRs.

ADCCON Register

Name: ADCCON
 Address: 0xFFFF0500
 Default Value: 0x0600
 Access: Read/write

ADCCON is an ADC control register that allows the programmer to enable the ADC peripheral, select the mode of operation of the ADC (either in single-ended mode, pseudo differential mode, or fully differential mode), and select the conversion type. This MMR is described in Table 28.

Table 28. ADCCON MMR Bit Designations

Bit	Value	Description
15:14		Reserved.
13		Set by the user to enable edge trigger mode. Cleared by the user to enable level trigger mode.
12:10		ADC clock speed.
	000	$f_{ADC}/1$. This divider is provided to obtain 1 MSPS ADC with an external clock <41.78 MHz.
	001	$f_{ADC}/2$ (default value).
	010	$f_{ADC}/4$.
	011	$f_{ADC}/8$.
	100	$f_{ADC}/16$.
	101	$f_{ADC}/32$.
9:8		ADC acquisition time.
	00	Two clocks.
	01	Four clocks.
	10	Eight clocks (default value).
	11	16 clocks.
7		Enable start conversion. Set by the user to start any type of conversion command. Cleared by the user to disable a start conversion (clearing this bit does not stop the ADC when continuously converting).
6		Enable ADC _{BUSY} . Set by the user to enable the ADC _{BUSY} pin. Cleared by the user to disable the ADC _{BUSY} pin.
5		ADC power control. Set by the user to place the ADC in normal mode (the ADC must be powered up for at least 5 μ s before it converts correctly). Cleared by the user to place the ADC in power-down mode.
4:3		Conversion mode.
	00	Single-ended mode.
	01	Differential mode.
	10	Pseudo differential mode.
	11	Reserved.

ADuC7124

Bit	Value	Description
2:0		Conversion type.
	000	Enable CONV _{START} pin as a conversion input.
	001	Enable Timer1 as a conversion input.
	010	Enable Timer0 as a conversion input.
	011	Single software conversion. Sets to 000 after conversion (note that Bit 7 of ADCCON MMR should be cleared after starting a single software conversion to avoid further conversions triggered by the CONV _{START} pin).
	100	Continuous software conversion.
	101	PLA conversion.
	Other	Reserved.

ADCCP Register

Name:	ADCCP
Address:	0xFFFF0504
Default Value:	0x00
Access:	Read/write

ADCCP is an ADC positive channel selection register. This MMR is described in Table 29.

Table 29. ADCCP¹ MMR Bit Designation

Bit	Value	Description
7:5		Reserved.
4:0		Positive channel selection bits.
	00000	ADC0.
	00001	ADC1.
	00010	ADC2.
	00011	ADC3.
	00100	ADC4.
	00101	ADC5.
	00110	ADC6.
	00111	ADC7.
	01000	ADC8.
	01001	ADC9.
	01010	ADC10.
	01011	ADC11.
	01100	ADC12/DAC0.
	01101	ADC13/DAC1.
	01110	ADC14/DAC2.
	01111	ADC15/DAC3.
	10000	Temperature sensor.
	10001	AGND (self-diagnostic feature).
	10010	Internal reference (self-diagnostic feature).
10011	AV _{DD} /2.	
Others	Reserved.	

¹ ADC and DAC channel availability depends on part model. See the Ordering Guide for details.

ADCCN Register

Name:	ADCCN
Address:	0xFFFF0508
Default Value:	0x01
Access:	Read/write

ADCCN is an ADC negative channel selection register. This MMR is described in Table 30.

Table 30. ADCCN MMR Bit Designation

Bit	Value	Description
7:5		Reserved.
4:0		Negative channel selection bits.
	00000	ADC0.
	00001	ADC1.
	00010	ADC2.
	00011	ADC3.
	00100	ADC4.
	00101	ADC5.
	00110	ADC6.
	00111	ADC7.
	01000	ADC8.
	01001	ADC9.
	01010	ADC10.
	01011	ADC11.
	01100	ADC12/DAC0.
	01101	ADC13/DAC1.
	01110	ADC14/DAC2.
	01111	ADC15/DAC3.
	10000	Reserved.
	10001	AGND.
	10010	Reserved.
10011	Reserved.	
Others	Reserved.	

ADCSTA Register

Name:	ADCSTA
Address:	0xFFFF050C
Default Value:	0x00
Access:	Read only

ADCSTA is an ADC status register that indicates when an ADC conversion result is ready. The ADCSTA register contains only one bit, ADCReady (Bit 0), representing the status of the ADC. This bit is set at the end of an ADC conversion, generating an ADC interrupt. It is cleared automatically by reading the ADCDAT MMR. When the ADC is performing a conversion, the status of the ADC can be read externally via the ADC_{BUSY} pin. This pin is high during a conversion. When the conversion is finished, ADC_{BUSY} goes back low. This information is available

on P0.5 (see the General-Purpose Input/Output section) if enabled in the ADCCON register.

ADCDAT Register

Name:	ADCDAT
Address:	0xFFFF0510
Default Value:	0x00000000
Access:	Read only

ADCDAT is an ADC data result register that holds the 12-bit ADC result, as shown in Figure 29.

ADCRST Register

Name:	ADCRST
Address:	0xFFFF0514
Default Value:	0x00
Access:	Read/write

ADCRST resets the digital interface of the ADC. Writing any value to this register resets all the ADC registers to their default values.

ADCGN Register

Name:	ADCGN
Address:	0xFFFF0530
Default Value:	0x0200
Access:	Read/write

ADCGN is a 10-bit gain calibration register.

ADCOF Register

Name:	ADCOF
Address:	0xFFFF0534
Default Value:	0x0200
Access:	Read/write

ADCOF is a 10-bit offset calibration register.

CONVERTER OPERATION

The ADC incorporates a successive approximation (SAR) architecture involving a charge-sampled input stage. This architecture can operate in three different modes: differential, pseudo differential, and single-ended.

Differential Mode

The ADuC7124 contains a successive approximation ADC based on two capacitive DACs. Figure 31 and Figure 32 show simplified schematics of the ADC in acquisition and conversion phases, respectively. The ADC comprises control logic, a SAR, and two capacitive DACs. In Figure 31 (the acquisition phase), SW3 is closed and SW1 and SW2 are in Position A. The

comparator is held in a balanced condition, and the sampling capacitor arrays acquire the differential signal on the input.

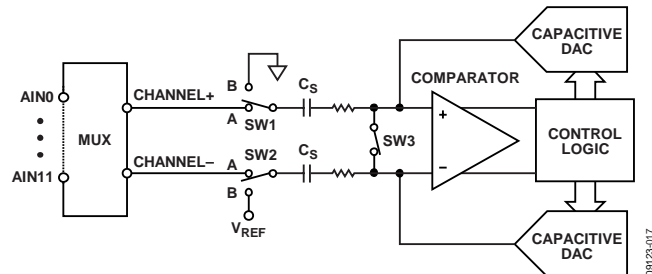

Figure 31. ADC Acquisition Phase

When the ADC starts a conversion, as shown in Figure 32, SW3 opens, and then SW1 and SW2 move to Position B. This causes the comparator to become unbalanced. Both inputs are disconnected once the conversion begins. The control logic and the charge redistribution DACs are used to add and subtract fixed amounts of charge from the sampling capacitor arrays to bring the comparator back into a balanced condition. When the comparator is rebalanced, the conversion is complete. The control logic generates the ADC output code. The output impedances of the sources driving the V_{IN+} and V_{IN-} pins must be matched; otherwise, the two inputs have different settling times, resulting in errors.

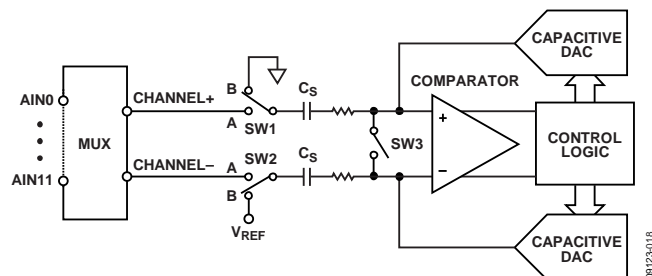

Figure 32. ADC Conversion Phase

Pseudo Differential Mode

In pseudo differential mode, Channel- is linked to the ADCNEG pin of the ADuC7124. In Figure 33, ADCNEG is represented as V_{IN-} . SW2 switches between A (Channel-) and B (V_{REF}). The ADCNEG pin must be connected to ground or to a low voltage. The input signal on V_{IN+} can then vary from V_{IN-} to $V_{REF} + V_{IN-}$. Note that V_{IN-} must be chosen so that $V_{REF} + V_{IN-}$ do not exceed AV_{DD} .

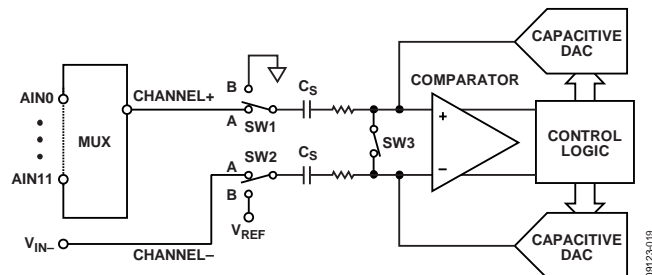

Figure 33. ADC in Pseudo Differential Mode

ADuC7124

Single-Ended Mode

In single-ended mode, SW2 is always connected internally to ground. The V_{IN-} pin can be floating. The input signal range on V_{IN+} is 0 V to V_{REF} .

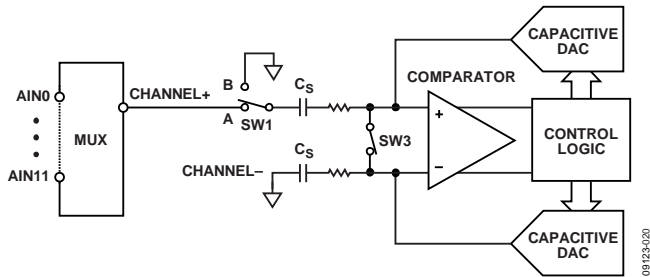

Figure 34. ADC in Single-Ended Mode

Analog Input Structure

Figure 35 shows the equivalent circuit of the analog input structure of the ADC. The four diodes provide ESD protection for the analog inputs. Care must be taken to ensure that the analog input signals never exceed the supply rails by more than 300 mV; this can cause these diodes to become forward-biased and start conducting into the substrate. These diodes can conduct up to 10 mA without causing irreversible damage to the part.

The C1 capacitors in Figure 35 are typically 4 pF and can be primarily attributed to pin capacitance. The resistors are lumped components made up of the on resistance of the switches. The value of these resistors is typically about 100 Ω . The C2 capacitors are the sampling capacitors of the ADC and typically have a capacitance of 16 pF.

Figure 35. Equivalent Analog Input Circuit Conversion Phase: Switches Open, Track Phase: Switches Closed

Table 31. V_{CM} Ranges

AV_{DD}	V_{REF}	V_{CM} Min	V_{CM} Max	Signal Peak-to-Peak
3.3 V	2.5 V	1.25 V	2.05 V	2.5 V
	2.048 V	1.024 V	2.276 V	2.048 V
	1.25 V	0.75 V	2.55 V	1.25 V
3.0 V	2.5 V	1.25 V	1.75 V	2.5 V
	2.048 V	1.024 V	1.976 V	2.048 V
	1.25 V	0.75 V	2.25 V	1.25 V

For ac applications, removing high frequency components from the analog input signal is recommended by using an RC low-pass filter on the relevant analog input pins. In applications where harmonic distortion and signal-to-noise ratio are critical, the analog input should be driven from a low impedance source. Large source impedances significantly affect the ac performance of the ADC. This can necessitate the use of an input buffer amplifier. The choice of the op amp is a function of the particular application. Figure 36 and Figure 37 give an example of the ADC front end.

Figure 36. Buffering Single-Ended/Pseudo Differential Input

Figure 37. Buffering Differential Inputs

When no amplifier is used to drive the analog input, the source impedance should be limited to values lower than 1 k Ω . The maximum source impedance depends on the amount of total harmonic distortion (THD) that can be tolerated. The THD increases as the source impedance increases and the performance degrades.

DRIVING THE ANALOG INPUTS

Internal or external references can be used for the ADC. In differential mode of operation, there are restrictions on the common-mode input signal (V_{CM}), which is dependent upon the reference value and supply voltage used to ensure that the signal remains within the supply rails. Table 31 gives some calculated V_{CM} minimum and V_{CM} maximum values.

CALIBRATION

By default, the factory-set values written to the ADC offset (ADCOF) and gain coefficient registers (ADCGN) yield optimum performance in terms of end-point errors and linearity for standalone operation of the part (see the Specifications section). If system calibration is required, it is possible to modify the default offset and gain coefficients to improve end-point errors, but note that any modification to the factory-set ADCOF and ADCGN values can degrade ADC linearity performance.

For system offset error correction, the ADC channel input stage must be tied to AGND. A continuous software ADC conversion loop must be implemented by modifying the value in ADCOF until the ADC result (ADCDAT) reads Code 0 to Code 1. If the ADCDAT value is greater than 1, ADCOF should be decremented until ADCDAT reads Code 0 to Code 1. Offset error correction is done digitally and has a resolution of 0.25 LSB and a range of $\pm 3.125\%$ of V_{REF} .

For system gain error correction, the ADC channel input stage must be tied to V_{REF} . A continuous software ADC conversion loop must be implemented to modify the value in ADCGN until the ADC result (ADCDAT) reads Code 4094 to Code 4095. If the ADCDAT value is less than 4094, ADCGN should be incremented until ADCDAT reads Code 4094 to Code 4095. Similar to the offset calibration, the gain calibration resolution is 0.25 LSB with a range of $\pm 3\%$ of V_{REF} .

TEMPERATURE SENSOR

The ADuC7124 provides voltage outputs from an on-chip band gap reference that is proportional to absolute temperature. This voltage output can also be routed through the front-end ADC multiplexer (effectively, an additional ADC channel input), facilitating an internal temperature sensor channel, measuring die temperature.

An ADC temperature sensor conversion differs from a standard ADC voltage. The ADC performance specifications do not apply to the temperature sensor.

Chopping of the internal amplifier must be enabled using the TSCON register. To enable this mode, the user must set Bit 0 of TSCON. The user must also take two consecutive ADC readings and average them in this mode.

The ADCCON register must be configured to 0x37A3.

To calculate die temperature, use the following formula:

$$T - T_{REF} = (V_{ADC} - V_{TREF}) \times K$$

where:

T is the temperature result.

$T_{REF} = 25^\circ\text{C}$. For the ADuC7124, V_{TREF} is 1.415 V, which corresponds to $T_{REF} = 25^\circ\text{C}$ as described in Table 1.

V_{ADC} is the average ADC result from two consecutive conversions.

K is the gain of the ADC in temperature sensor mode as determined by characterization data. $K = 0.2555^\circ\text{C}/\text{mV}$. This corresponds to the 1/voltage T_c specification from Table 1.

Using the default values from Table 1 and without any calibration, this equation becomes

$$T - 25^\circ\text{C} = (V_{ADC} - 1415) \times 0.2555$$

where V_{ADC} is in mV.

For better accuracy, the user should perform a single point calibration at a controlled temperature value.

For the calculation with no calibration above, use 25°C and 1415 mV. The idea of a single point calibration is to use other known (T_{REF} , V_{TREF}) values to replace the common = 25°C and 1415 mV for every part.

For some users, it is not possible to get such a known pair.

For such cases, the ADuC7124 comes with a single point calibration value loaded in the TEMPREF register. For more details on this register, see Table 33. During production testing of the ADuC7124, the TEMPREF register is loaded with an offset adjustment factor. Each part has a different value in the TEMPREF register. Using this single point calibration, the same formula is still used.

$$T - T_{REF} = (V_{ADC} - V_{TREF}) \times K$$

where:

$T_{REF} = 25^\circ\text{C}$ but is not guaranteed.

V_{TREF} can be calculated using the TEMPREF register.

TSCON Register

Name:	TSCON
Address:	0xFFFF0544
Default Value:	0x00
Access:	Read/write

Table 32. TSCON MMR Bit Designations

Bit	Description
7 to 1	Reserved.
0	Temperature sensor chop enable bit. This bit must be set. This bit is set to 1 to enable chopping of the internal amplifier to the ADC. This bit is cleared to disable chopping. This results in incorrect temperature sensor readings. This bit is cleared by default.

ADuC7124

TEMPREF Register

Name:	TEMPREF
Address:	0xFFFF0548
Default Value:	0XXXXX
Access:	Read/write

Table 33. TEMPREF MMR Bit Designations

Bit	Description
15 to 9	Reserved.
8	Temperature reference voltage sign.
7 to 0	Temperature sensor offset calibration voltage. To calculate the V_{TEMP} from the TEMPREF register, perform the following calculation: If TEMPREF sign is negative, $C_{TREF} = 2292 - TEMPREF[7:0]$ where: TEMPREF[8] = 1 Or If TEMPREF sign is positive, $C_{TREF} = TEMPREF[7:0] + 2292$ where: TEMPREF[8] = 0. Finally, $V_{TREF} = ((C_{TREF} \times V_{REF}) / 4096) \times 1000$ Insert V_{TREF} into $T - T_{REF} = (V_{ADC} - V_{TREF}) \times K$ Note that the ADC code value 2292 is a default value when using the TEMPREF register. It is not an exact value and must only be used with the TEMPREF register.

BAND GAP REFERENCE

Each ADuC7124 provides on-chip band gap references of 2.5 V, which can be used for the ADC and DAC. This internal reference also appears on the V_{REF} pin. When using the internal reference, a 0.47 μ F capacitor must be connected from the external V_{REF} pin to AGND to ensure stability and fast response during ADC conversions. This reference can also be connected to an external

pin (V_{REF}) and used as a reference for other circuits in the system. An external buffer is required because of the low drive capability of the V_{REF} output (<5 μ A). A programmable option also allows an external reference input on the V_{REF} pin. Note that it is not possible to disable the internal reference. Therefore, the external reference source must be capable of overdriving the internal reference source.

REFCON Register

Name:	REFCON
Address:	0xFFFF048C
Default Value:	0x00
Access:	Read/write

The band gap reference interface consists of an 8-bit MMR REFCON, described in Table 34.

Table 34. REFCON MMR Bit Designations

Bit	Description
7:2	Reserved.
1	Internal reference power-down bit. Set this bit to 1 to power down the internal reference source. This bit should be set when connecting an external reference source. Clear this bit to enable the internal reference. This bit is cleared by default.
0	Internal reference output enable. Set by the user to connect the internal 2.5 V reference to the V_{REF} pin. The reference can be used for external component but must be buffered. Cleared by the user to disconnect the reference from the V_{REF} pin.

To connect an external reference source to the ADuC7124, configure REFCON = 0x00. ADC and the DACs can be configured to use same or a different reference resource (see Table 64).

NONVOLATILE FLASH/EE MEMORY

The ADuC7124 incorporates Flash/EE memory technology on-chip to provide the user with nonvolatile, in-circuit reprogrammable memory space.

Like EEPROM, flash memory can be programmed in-system at a byte level, although it must first be erased. The erase is performed in page blocks. As a result, flash memory is often and more correctly referred to as Flash/EE memory.

Overall, Flash/EE memory represents a step closer to the ideal memory device that includes nonvolatility, in-circuit programmability, high density, and low cost. Incorporated in the ADuC7124, Flash/EE memory technology allows the user to update program code space in-circuit, without the need to replace one-time programmable (OTP) devices at remote operating nodes.

Flash/EE Memory

The ADuC7124 contains two 64 kB arrays of Flash/EE memory. In the first block, the lower 62 kB is available to the user, and the upper 2 kB of this Flash/EE program memory array contain permanently embedded firmware, allowing in-circuit serial download. The 2 kB of embedded firmware also contain a power-on configuration routine that downloads factory calibrated coefficients to the various calibrated peripherals (band gap references and so on). This 2 kB embedded firmware is hidden from user code. It is not possible for the user to read, write, or erase this page. In the second block, all 64 kB of Flash/EE memory are available to the user.

The 126 kB of Flash/EE memory can be programmed in-circuit, using the serial download mode or the JTAG mode provided.

Flash/EE Memory Reliability

The Flash/EE memory arrays on the parts are fully qualified for two key Flash/EE memory characteristics: Flash/EE memory cycling endurance and Flash/EE memory data retention.

Endurance quantifies the ability of the Flash/EE memory to be cycled through many program, read, and erase cycles. A single endurance cycle is composed of four independent, sequential events, defined as

1. Initial page erase sequence.
2. Read/verify sequence (single Flash/EE).
3. Byte program sequence memory.
4. Second read/verify sequence (endurance cycle).

In reliability qualification, every half word (16-bit wide) location of the three pages (top, middle, and bottom) in the Flash/EE memory is cycled 10,000 times from 0x0000 to 0xFFFF. As indicated in Table 1, the Flash/EE memory endurance qualification is carried out in accordance with JEDEC Retention Lifetime Specification A117 over the industrial temperature range of -40° to $+125^{\circ}\text{C}$. The results allow the specification of a minimum endurance figure over a supply temperature of 10,000 cycles.

Retention quantifies the ability of the Flash/EE memory to retain its programmed data over time. Again, the parts are qualified in accordance with the formal JEDEC Retention Lifetime Specification (A117) at a specific junction temperature ($T_j = 85^{\circ}\text{C}$). As part of this qualification procedure, the Flash/EE memory is cycled to its specified endurance limit (see the Flash/EE Memory section) before data retention is characterized. This means that the Flash/EE memory is guaranteed to retain its data for its fully specified retention lifetime every time the Flash/EE memory is reprogrammed. In addition, note that retention lifetime, based on the activation energy of 0.6 eV, derates with T_j , as shown in Figure 38.

Figure 38. Flash/EE Memory Data Retention

PROGRAMMING

The 62 kB of Flash/EE memory can be programmed in-circuit, using the serial download mode or the provided JTAG mode.

Serial Downloading (In-Circuit Programming)

The ADuC7124 facilitates code download via the standard UART serial port. The parts enter serial download mode after a reset or power cycle if the BM pin is pulled low through an external 1 k Ω resistor. Once in serial download mode, the user can download code to the full 126 kB of Flash/EE memory while the device is in-circuit in its target application hardware. An executable PC serial download is provided as part of the development system for serial downloading via the UART. The AN-724 application note describes the UART download protocol.

JTAG Access

The JTAG protocol uses the on-chip JTAG interface to facilitate code download and debug.

To access the part via the JTAG interface, the P0.0/BM pin must be set high.

When debugging, user code should not write to the P0.1, P0.2, and P0.3 pins. If user code toggles any of these pins, JTAG debug pods are not able to connect to the ADuC7124. If this happens, mass erase the part using the UART downloader.

FLASH/EE MEMORY SECURITY

The 126 kB of Flash/EE memory available to the user can be read and write protected. Bit 31 of the FEE0PRO/FEE0HID MMR protects the 126 kB from being read through JTAG and also in UART programming mode. The other 31 bits of this register protect writing to the Flash/EE memory; each bit protects four pages, that is, 2 kB. Write protection is activated for all access types. FEE1PRO and FEE1HID, similarly, protect the second 64 kB block. All 32 bits of this are used to protect four pages at a time.

Three Levels of Protection

- Protection can be set and removed by writing directly into FEE0HID MMR. This protection does not remain after reset.
- Protection can be set by writing into FEE0PRO MMR. It takes effect only after a save protection command (0x0C) and a reset. The FEE0PRO MMR is protected by a key to avoid direct access. The key is saved once and must be entered again to modify FEE0PRO. A mass erase sets the key back to 0xFFFF but also erases all the user code.
- Flash can be permanently protected by using the FEE1PRO MMR and a particular value of key: 0xDEADDEAD. Entering the key again to modify the FEE1PRO register is not allowed.

Sequence to Write the Key

1. Write the bit in FEE0PRO corresponding to the page to be protected.
2. Enable key protection by setting Bit 6 of FEE0MOD (Bit 5 must equal 0).
3. Write a 32-bit key in FEE0ADR and FEE0DAT.
4. Run the write key command 0x0C in FEE0CON; wait for the read to be successful by monitoring FEE0STA.
5. Reset the part.

To remove or modify the protection, the same sequence is used with a modified value of FEE0PRO. If the key chosen is the value 0xDEAD, the memory protection cannot be removed. Only a mass erase unprotects the part, but it also erases all user code.

The sequence to write the key is illustrated in the following example (this protects writing Page 4 to Page 7 of the Flash):

```
FEE0PRO=0xFFFFFFFF; //Protect Page 4 to
Page 7
FEE0MOD=0x48; //Write key enable
FEE0ADR=0x1234; //16 bit key value
FEE0DAT=0x5678; //16 bit key value
FEE0CON= 0x0C; //Write key command
```

The same sequence should be followed to protect the part permanently with FEE0ADR = 0xDEAD and FEE0DAT = 0xDEAD.

FLASH/EE CONTROL INTERFACE

Table 35. FEE0DAT Register

Name	Address	Default Value	Access
FEE0DAT	0xFFFFF80C	0XXXX	R/W

Bit	Description
7:5	Reserved.
4	Flash/EE interrupt enable. Set by the user to enable the Flash/EE interrupt. The interrupt occurs when a command is complete. Cleared by the user to disable the Flash/EE interrupt.
3	Erase/write command protection. Set by the user to enable the erase and write commands. Cleared to protect the Flash/EE memory against the erase/write command.
2	Reserved. Should always be set to 0 by the user.
1:0	Flash/EE wait states. Both Flash/EE blocks must have the same wait state value for any change to take effect.

Table 53. Command Codes in FEEExCON

Code	Command	Description
0x00 ¹	Null	Idle state.
0x01 ¹	Single read	Load FEEExDAT with the 16-bit data indexed by FEEExADR.
0x02 ¹	Single write	Write FEEExDAT at the address pointed to by FEEExADR. This operation takes 50 μ s.
0x03 ¹	Erase/write	Erase the page indexed by FEEExADR and write FEEExDAT at the location pointed to by FEEExADR. This operation takes 20 ms.
0x04 ¹	Single verify	Compare the contents of the location pointed to by FEEExADR to the data in FEEExDAT. The result of the comparison is returned in FEEExSTA Bit 1.
0x05 ¹	Single erase	Erase the page indexed by FEEExADR.
0x06 ¹	Mass erase	Erase user space. The 2 kB of kernel are protected in Block 0. This operation takes 2.48 sec. To prevent accidental execution, a command sequence is required to execute this instruction.
0x07	Reserved	Reserved.
0x08	Reserved	Reserved.
0x09	Reserved	Reserved.
0x0A	Reserved	Reserved.
0x0B	Signature	Gives a signature of the 64 kB of Flash/EE in the 24-bit FEEExSIGN MMR. This operation takes 32,778 clock cycles.
0x0C	Protect	This command can be run only once. The value of FEEExPRO is saved and can be removed only with a mass erase (0x06) or with the key.
0x0D	Reserved	Reserved.
0x0E	Reserved	Reserved.
0x0F	Ping	No operation, interrupt generated.

¹ The FEEExCON register always reads 0x07 immediately after execution of any of these commands.

30:0	Write protection for Page 123 to Page 120, for Page 119 to Page 116, and for Page 0 to Page 3. Cleared by the user to protect the pages in writing. Set by the user to allow writing to the pages.

Table 55. FEE1PRO and FEE1HID MMR Bit Designations

Bit	Description
31	Read protection. Cleared by the user to protect Block 1. Set by the user to allow reading of Block 1.
30	Write protection for Page 127 to Page 120. Cleared by the user to protect the pages in writing. Set by the user to allow writing to the pages.
29:0	Write protection for Page 119 to Page 116 and for Page 0 to Page 3. Cleared by the user to protect the pages in writing. Set by the user to allow writing to the pages.

EXECUTION TIME FROM SRAM AND FLASH/EE

This section describes SRAM and Flash/EE access times during execution for applications where execution time is critical.

Execution from SRAM

Fetching instructions from SRAM takes one clock cycle because the access time of the SRAM is 2 ns, and a clock cycle is 24 ns minimum. However, if the instruction involves reading or writing data to memory, one extra cycle must be added if the data is in SRAM (or three cycles if the data is in Flash/EE): one cycle to execute the instruction and two cycles to get the 32-bit data from Flash/EE. A control flow instruction (a branch instruction, for example) takes one cycle to fetch but also takes two cycles to fill the pipeline with the new instructions.

Execution from Flash/EE

Because the Flash/EE width is 16 bits and access time for 16-bit words is 22 ns, execution from Flash/EE cannot be done in one cycle (as can be done from SRAM when the CD bit = 0). Also, some dead times are needed before accessing data for any value of the CD bits.

In ARM mode, where instructions are 32 bits, two cycles are needed to fetch any instruction when CD = 0. In Thumb mode, where instructions are 16 bits, one cycle is needed to fetch any instruction.

Timing is identical in both modes when executing instructions that involve using the Flash/EE for data memory. If the instruction to be executed is a control flow instruction, an extra cycle is needed to decode the new address of the program counter, and then four cycles are needed to fill the pipeline. A data processing instruction involving only the core register does not require any extra clock cycles. However, if it involves data in

Flash/EE, an extra clock cycle is needed to decode the address of the data, and two cycles are needed to get the 32-bit data from Flash/EE. An extra cycle must also be added before fetching another instruction. Data transfer instructions are more complex and are summarized in Table 56.

Table 56. Execution Cycles in ARM/Thumb Mode

Instructions	Fetch Cycles	Dead Time	Data Access	Dead Time
LD ¹	2/1	1	2	1
LDH	2/1	1	1	1
LDM/PUSH	2/1	N ²	2 × N ²	N ¹
STR ¹	2/1	1	2 × 20 ns	1
STRH	2/1	1	20 ns	1
STRM/POP	2/1	N ¹	2 × N × 20 ns ¹	N ¹

¹ The SWAP instruction combines an LD and STR instruction with only one fetch, giving a total of eight cycles + 40 ns.

² N is the number of data bytes to load or store in the multiple load/store instruction (1 < N ≤ 16).

RESET AND REMAP

The ARM exception vectors are all situated at the bottom of the memory array, from Address 0x00000000 to Address 0x00000020, as shown in Figure 39.

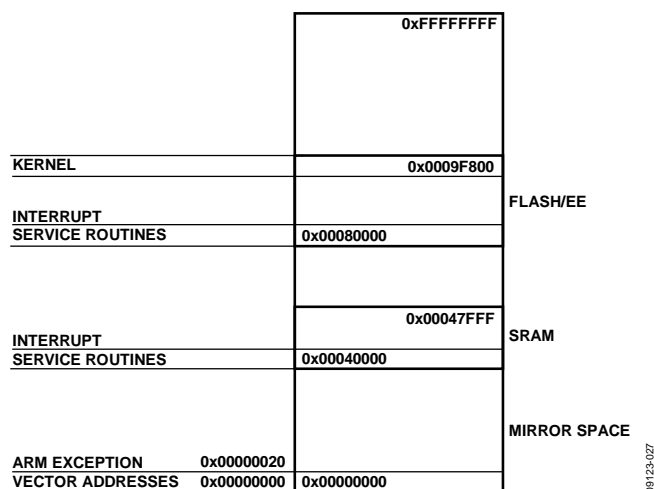

Figure 39. Remap for Exception Execution

By default, and after any reset, the Flash/EE is mirrored at the bottom of the memory array. The remap function allows the programmer to mirror the SRAM at the bottom of the memory array, which facilitates execution of exception routines from SRAM instead of from Flash/EE. This means exceptions are executed twice as fast, being executed in 32-bit ARM mode with 32-bit wide SRAM instead of 16-bit wide Flash/EE memory.

ADuC7124

Table 57. REMAP MMR Bit Designations (Address = 0xFFFF0220. Default Value = 0x00)

Bit	Name	Description
0	Remap	Remap bit. Set by the user to remap the SRAM to Address 0x00000000. Cleared automatically after reset to remap the Flash/EE memory to address 0x00000000.

Remap Operation

When a reset occurs on the ADuC7124, execution automatically starts in factory programmed, internal configuration code. This kernel is hidden and cannot be accessed by user code. If the part is in normal mode (BM pin is high), it executes the power-on configuration routine of the kernel and then jumps to the reset vector address, 0x00000000, to execute the reset exception routine of the user.

Because the Flash/EE is mirrored at the bottom of the memory array at reset, the reset interrupt routine must always be written in Flash/EE.

The remap is done from Flash/EE by setting Bit 0 of the REMAP register. Caution must be taken to execute this command from Flash/EE, above Address 0x00080020, and not from the bottom of the array, because this is replaced by the SRAM.

This operation is reversible. The Flash/EE can be remapped at Address 0x00000000 by clearing Bit 0 of the REMAP MMR. Caution must again be taken to execute the remap function from outside the mirrored area. Any type of reset remaps the Flash/EE memory at the bottom of the array.

Reset Operation

There are four kinds of reset: external, power-on, watchdog expiration, and software force. The RSTSTA register indicates the source of the last reset, and RSTCLR allows clearing of the RSTSTA register. These registers can be used during a reset exception service routine to identify the source of the reset. If RSTSTA is null, the reset is external.

The RSTCFG register allows different peripherals to retain their state after a watchdog or software reset.

RSTSTA Register

Name:	RSTSTA
Address:	0xFFFF0230
Default Value:	0x01
Access:	Read only

Table 58. RSTSTA MMR Bit Designations

Bit	Description
7:3	Reserved.
2	Software reset. Set by the user to force a software reset. Cleared by setting the corresponding bit in RSTCLR.
1	Watchdog timeout. Set automatically when a watchdog timeout occurs. Cleared by setting the corresponding bit in RSTCLR.
0	Power-on reset. Set automatically when a power-on reset occurs. Cleared by setting the corresponding bit in RSTCLR.

RSTCLR Register

Name:	RSTCLR
Address:	0xFFFF0234
Default Value:	0x00
Access:	Write only

Note that to clear the RSTSTA register, users must write the Value 0x07 to the RSTCLR register.

RSTCFG Register

Name:	RSTCFG
Address:	0xFFFF024C
Default Value:	0x05
Access:	Read/write

RSTCFG MMR Bit Designations

Bit	Description
7:3	Reserved. Always set to 0.
2	This bit is set to 1 to configure the DAC outputs to retain their state after a watchdog or software reset. This bit is cleared for the DAC pins and registers to return to their default state.
1	Reserved. Always set to 0.
0	This bit is set to 1 to configure the GPIO pins to retain their state after a watchdog or software reset. This bit is cleared for the GPIO pins and registers to return to their default state.

RSTKEY0 Register

Name:	RSTKEY0
Address:	0xFFFF0248
Default Value:	N/A
Access:	Write only

RSTKEY1 Register

Name: RSTKEY1
Address: 0xFFFF0250
Default Value: N/A
Access: Write only

OTHER ANALOG PERIPHERALS

DAC

The ADuC7124 incorporates two 12-bit voltage output DACs on-chip. Each DAC has a rail-to-rail voltage output buffer capable of driving 5 kΩ/100 pF.

Each DAC has three selectable ranges: 0 V to V_{REF} (internal band gap 2.5 V reference), 0 V to DAC_{REF} , and 0 V to AV_{DD} . DAC_{REF} is equivalent to an external reference for the DAC. The signal range is 0 V to AV_{DD} .

MMRs Interface

Each DAC is independently configurable through a control register and a data register. These two registers are identical for the two DACs. Only DAC0CON (see Table 61) and DAC0DAT (see Table 63) are described in detail in this section.

Table 60. DACxCON Registers

Name	Address	Default Value	Access
DAC0CON	0xFFFF0600	0x00	R/W
DAC1CON	0xFFFF0608	0x00	R/W

Table 61. DAC0CON MMR Bit Designations

Bit	Value	Name	Description
7:6			Reserved.
5		DACCLK	DAC update rate. Set by the user to update the DAC using Timer1. Cleared by the user to update the DAC using HCLK (core clock).
4		DACCLR	DAC clear bit. Set by the user to enable normal DAC operation. Cleared by the user to reset the data register of the DAC to 0.
3			Reserved. This bit should be left at 0.
2			Reserved. This bit should be left at 0.
1:0			DAC range bits.
	00		Power-down mode. The DAC output is in tristate.
	01		0 V to DAC_{REF} range.
	10		0 V to V_{REF} (2.5 V) range.
	11		0 V to AV_{DD} range.

Table 63. DAC0DAT MMR Bit Designations

Bit	Description
31:28	Reserved.
27:16	12-bit data for DAC0.
15:0	Reserved.

Using the DACs

The on-chip DAC architecture consists of a DAC resistor string followed by an output buffer amplifier. The functional equivalent is shown in Figure 40.

Figure 40. DAC Structure

As illustrated in Figure 40, the reference source for each DAC is user selectable in software. It can be either AV_{DD} , V_{REF} , or DAC_{REF} . In 0-to- AV_{DD} mode, the DAC output transfer function spans from 0 V to the voltage at the AV_{DD} pin. In 0-to- DAC_{REF} mode, the DAC output transfer function spans from 0 V to the voltage at the DAC_{REF} pin. In 0-to- V_{REF} mode, the DAC output transfer function spans from 0 V to the internal 2.5 V reference, V_{REF} .

The DAC output buffer amplifier features a true, rail-to-rail output stage implementation. This means that, when unloaded, each output is capable of swinging to within less than 5 mV of both AV_{DD} and ground. Moreover, the DAC linearity specification (when driving a 5 kΩ resistive load to ground) is guaranteed through the full transfer function except the 0 to 100 codes, and, in 0-to- AV_{DD} mode only, Code 3995 to Code 4095.

Linearity degradation near ground and V_{DD} is caused by saturation of the output amplifier, and a general representation of its effects (neglecting offset and gain error) is illustrated in Figure 41. The dotted line in Figure 41 indicates the ideal transfer function, and the solid line represents what the transfer function may look like with endpoint nonlinearities due to saturation of the output amplifier. Note that Figure 41 represents a transfer function in 0-to- AV_{DD} mode only. In 0-to- V_{REF} or 0-to- DAC_{REF} mode (with $V_{REF} < AV_{DD}$ or $DAC_{REF} < AV_{DD}$), the lower nonlinearity is similar. However, the upper portion of the transfer function follows the ideal line right to the end (V_{REF} in this case, not AV_{DD}), showing no signs of endpoint linearity errors.

Figure 41. Endpoint Nonlinearities Due to Amplifier Saturation

The endpoint nonlinearities conceptually illustrated in Figure 41 get worse as a function of output loading. Most of the ADuC7124 data sheet specifications assume a 5 k Ω resistive load to ground at the DAC output. As the output is forced to source or sink more current, the nonlinear regions at the top or bottom (respectively) of Figure 41 become larger. With larger current demands, this can significantly limit output voltage swing.

References to ADC and the DACs

ADC and DACs can be configured to use internal V_{REF} or external reference as a reference source. Internal V_{REF} must work with an external 0.47 μ F capacitor.

Table 64. Reference Source Selection for the ADC and DAC

REFCON.0	DACxCON[1:0]	Description
0	00	ADC works with an external reference. DACs are powered down.
0	01	ADC works with an external reference. DAC works with DAC_{REF} .
0	10	Reserved.
0	11	ADC works with an external reference. DACs work with internal AV_{DD} .
1	00	ADC works with an internal V_{REF} . DACs are power down.
1	01	ADC works with an external reference. DACs work with DAC_{REF} .
1	10	ADC and DACs work with an internal V_{REF} . ADC and DACs can also work with an external reference.
1	11	ADC works with an internal V_{REF} . DACs work with an internal AV_{DD} .

Note that if REFCON.1 = 1, the internal V_{REF} powers down and the ADC cannot use the internal V_{REF} even in Mode 1-xx.

Configuring DAC Buffers in Op Amp Mode

In op amp mode, the DAC output buffers are used as an op amp with the DAC itself disabled.

If DACBCFG Bit 0 is set, ADC0 is the positive input to the op amp, ADC1 is the negative input, and DAC0 is the output. In this mode, the DAC should be powered down by clearing Bit 0 and Bit 1 of DAC0CON.

If DACBCFG Bit 1 is set, ADC2 is the positive input to the op amp, ADC3 is the negative input, and DAC1 is the output. In this mode, the DAC should be powered down by clearing Bit 0 and Bit 1 of DAC1CON.

DACBCFG Register

Name:	DACBCFG
Address:	0xFFFF0654
Default Value:	0x00
Access:	Read/write

Table 65. DACBCFG MMR Bit Designations

Bit	Description
7:2	Reserved. Always set to 0.
1	Set this bit to 1 to configure the DAC1 output buffer in op amp mode. Clear this bit for the DAC buffer to operate as normal.
0	Set this bit to 1 to configure the DAC0 output buffer in op amp mode. Clear this bit for the DAC buffer to operate as normal.

DACBCFG Write Sequence

DACBCFG = user value.

POWER SUPPLY MONITOR

The power supply monitor regulates the IOV_{DD} supply on the ADuC7124. It indicates when the IOV_{DD} supply pin drops below one of two supply trip points. The monitor function is controlled via the PSMCON register. If enabled in the IRQEN or FIQEN register, the monitor interrupts the core using the PSMI bit in the PSMCON MMR. This bit is immediately cleared once CMP goes high.

This monitor function allows the user to save working registers to avoid possible data loss due to low supply or brown-out conditions. It also ensures that normal code execution does not resume until a safe supply level is established.

PSMCON Register

Name:	PSMCON
Address:	0xFFFF0440
Default Value:	0x0008
Access:	Read/write

Table 66. PSMCON MMR Bit Descriptions

Bit	Name	Description
3	CMP	Comparator bit. This is a read-only bit that directly reflects the state of the comparator. Read 1 indicates that the IOV _{DD} supply is above its selected trip point or, that the PSM is in power-down mode. Read 0 indicates that the IOV _{DD} supply is below its selected trip point. This bit should be set before leaving the interrupt service routine.
2	TP	Trip point selection bits. 0 = 2.79 V, 1 = 3.07 V.
1	PSMEN	Power supply monitor enable bit. Set to 1 to enable the power supply monitor circuit. Clear to 0 to disable the power supply monitor circuit.
0	PSMI	Power supply monitor interrupt bit. This bit is set high by the MicroConverter once CMP goes low, indicating low I/O supply. The PSMI bit can be used to interrupt the processor. Once CMP returns high, the PSMI bit can be cleared by writing a 1 to this location. A 0 write has no effect. There is no timeout delay; PSMI can be immediately cleared once CMP goes high.

COMPARATOR

The ADuC7124 integrates a voltage comparator. The positive input is multiplexed with ADC2, and the negative input has two options: ADC3 or DAC0. The output of the comparator can be configured to generate a system interrupt, be routed directly to the programmable logic array, start an ADC conversion, or be on an external pin, CMP_{OUT}, as shown in Figure 42.

Figure 42. Comparator

Hysteresis

Figure 43 shows how the input offset voltage and hysteresis terms are defined. Input offset voltage (V_{OS}) is the difference between the center of the hysteresis range and the ground level. This can either be positive or negative. The hysteresis voltage (V_H) is $\frac{1}{2}$ the width of the hysteresis range.

Figure 43. Comparator Hysteresis Transfer Function

Comparator Interface

The comparator interface consists of a 16-bit MMR, CMPCON, which is described in Table 67.

CMPCON Register

Name: CMPCON
 Address: 0xFFFF0444
 Default Value: 0x0000
 Access: Read/write

Table 67. CMPCON MMR Bit Descriptions

Bit	Value	Name	Description			
15:11			Reserved.			
10		CMPEN	Comparator enable bit. Set by the user to enable the comparator. Cleared by the user to disable the comparator.			
9:8		CMPIN	Comparator negative input select bits.			
	00			AV _{DD} /2.		
	01			ADC3 input.		
	10			DAC0 output.		
7:6		CMPOC	Comparator output configuration bits.			
	00			Reserved.		
	01			Reserved.		
	10			Output on CMP _{OUT} .		
5		CMPOL	Comparator output logic state bit. When low, the comparator output is high if the positive input (CMP0) is above the negative input (CMP1). When high, the comparator output is high if the positive input is below the negative input.			
	11			IRQ.		
	4:3				CMPRES	Response time.
				00		
4:3	11		3 μ s typical.			
	01/10		Reserved.			
2		CMPHYST	Comparator hysteresis sit. Set by user to have a hysteresis of about 7.5 mV. Cleared by user to have no hysteresis.			

Bit	Value	Name	Description
1		CMPORI	Comparator output rising edge interrupt. Set automatically when a rising edge occurs on the monitored voltage (CMP0). Cleared by user by writing a 1 to this bit.
0		CMPOFI	Comparator output falling edge interrupt. Set automatically when a falling edge occurs on the monitored voltage (CMP0). Cleared by user.

OSCILLATOR AND PLL—POWER CONTROL

Clocking System

The ADuC7124 integrates a 32.768 kHz $\pm 3\%$ oscillator, a clock divider, and a PLL. The PLL locks onto a multiple (1275) of the internal oscillator or an external 32.768 kHz crystal to provide a stable 41.78 MHz clock (UCLK) for the system. To allow power saving, the core can operate at this frequency or at binary submultiples of it. The actual core operating frequency, $UCLK/2^{CD}$, is referred to as HCLK. The default core clock is the PLL clock divided by 8 ($CD = 3$) or 5.22 MHz. The core clock frequency can also come from an external clock on the ECLK pin as described in Figure 44. The core clock can be output on ECLK when using an internal oscillator or external crystal.

Note that, when the ECLK pin is used to output the core clock, the output signal is not buffered and is not suitable for use as a clock source to an external device without an external buffer.

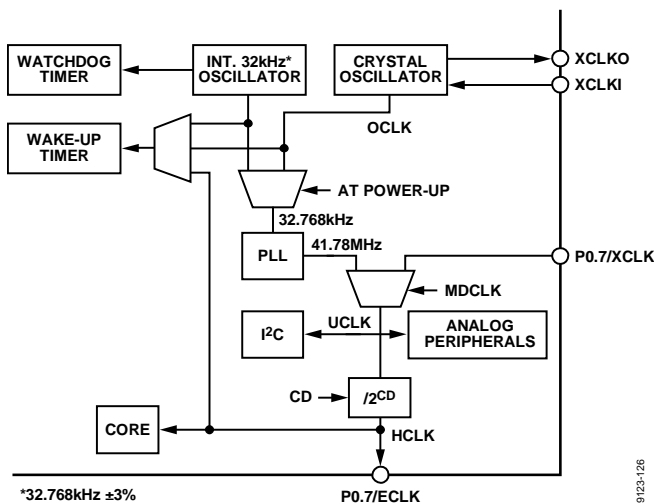

Figure 44. Clocking System

The selection of the clock source is in the PLLCON register. By default, the part uses the internal oscillator feeding the PLL.

External Crystal Selection

To switch to an external crystal, the user must follow this procedure:

1. Enable the Timer2 interrupt and configure it for a timeout period of $>120 \mu s$.
2. Follow the write sequence to the PLLCON register, setting the MDCLK bits to 01 and clearing the OSEL bit.
3. Force the part into NAP mode by following the correct write sequence to the POWCON0 register.
4. When the part is interrupted from NAP mode by the Timer2 interrupt source, the clock source has switched to the external clock.

Example source code:

```
T2LD = 5;
TCON = 0x480;
```

```
while ((T2VAL == t2val_old) || (T2VAL > 3))
//ensures timer value loaded

IRQEN = 0x10;
//enable T2 interrupt

PLLKEY1 = 0xAA;
PLLCON = 0x01;
PLLKEY2 = 0x55;

POWKEY1 = 0x01;
POWCON0 = 0x27; // Set core into nap mode
POWKEY2 = 0xF4;
```

In noisy environments, noise can couple to the external crystal pins, and PLL may lose lock momentarily. A PLL interrupt is provided in the interrupt controller. The core clock is immediately halted, and this interrupt is serviced only when the lock is restored.

In case of crystal loss, the watchdog timer should be used. During initialization, a test on the RSTSTA can determine if the reset came from the watchdog timer.

External Clock Selection

To switch to an external clock on P0.7, configure P0.7 in Mode 1. The external clock can be up to 41.78 MHz, providing the tolerance is 1%.

Example source code:

```
T2LD = 5;
TCON = 0x480;
```

```
while ((T2VAL == t2val_old) || (T2VAL > 3)) //ensures timer value loaded

IRQEN = 0x10;
//enable T2 interrupt

PLLKEY1 = 0xAA;
PLLCON = 0x03; //Select external clock
PLLKEY2 = 0x55;

POWKEY1 = 0x01;
POWCON0 = 0x27;
// Set core into nap mode
POWKEY2 = 0xF4;
```

ADuC7124

Power Control System

A choice of operating modes is available on the ADuC7124. Table 68 describes what part is powered on in the different modes and indicates the power-up time.

Table 69 gives some typical values of the total current consumption (analog + digital supply currents) in the different modes, depending on the clock divider bits. The AC, DAC, I²C, and SPI are turned off.

Table 68. Operating Modes

Mode	Core	Peripherals	PLL	XTAL/T2/T3	IRQ0 to IRQ3	Start-Up/Power-On Time
Active	On	On	On	On	On	66 ms at CD = 0
Pause		On	On	On	On	2.6 μs at CD = 0; 247 μs at CD = 7
Nap			On	On	On	2.6 μs at CD = 0; 247 μs at CD = 7
Sleep				On	On	1.58 ms
Stop					On	1.7 ms

Table 69. Typical Current Consumption at 25°C in mA, V_{DD} = 3.3 V

Mode	CD = 0	CD = 1	CD = 2	CD = 3	CD = 4	CD = 5	CD = 6	CD = 7
Active	33.3	23.1	15.4	11.6	9.7	8.8	8.3	8.1
Pause	20.6	12.7	8.8	6.8	5.8	5.3	5.1	4.9
Nap	4.6	4.6	4.6	4.6	4.6	4.6	4.6	4.6
Sleep	0.2	0.2	0.2	0.2	0.2	0.2	0.2	0.2
Stop	0.2	0.2	0.2	0.2	0.2	0.2	0.2	0.2

MMRs and Keys

The operating mode, clocking mode, and programmable clock divider are controlled via three MMRs, PLLCON (see Table 71), and POWCONx. PLLCON controls the operating mode of the clock system, POWCON0 controls the core clock frequency and the power-down mode, and POWCON1 controls the clock frequency to I²C and SPI.

To prevent accidental programming, a certain sequence must be followed to write to the PLLCON and POWCONx registers.

Table 70. PLLKEYx Registers

Name	Address	Default Value	Access
PLLKEY1	0xFFFF0410	0x0000	W
PLLKEY2	0xFFFF0418	0x0000	W

DIGITAL PERIPHERAL

GENERAL-PURPOSE INPUT/OUTPUT

The ADuC7124 provides 30 general-purpose, bidirectional I/O (GPIO) pins. All I/O pins are 5 V tolerant, meaning the GPIOs support an input voltage of 5 V.

In general, many of the GPIO pins have multiple functions (see the Pin Configuration and Function Descriptions section for pin function definitions). By default, the GPIO pins are configured in GPIO mode.

All GPIO pins have an internal pull-up resistor (of about 100 k Ω), and their drive capability is 1.6 mA. Note that a maximum of 20 GPIOs can drive 1.6 mA at the same time. Using the GPxPAR registers, it is possible to enable/disable the pull-up resistors for the following ports: P0.0, P0.4, P0.5, P0.6, P0.7, and the eight GPIOs of P1.

The 40 GPIOs are grouped in five ports, Port 0 to Port 4 (Port x). Each port is controlled by four or five MMRs.

Note that the kernel changes P0.6 from its default configuration at reset (MRST) to GPIO mode. If MRST is used for external circuitry, an external pull-up resistor should be used to ensure that the level on P0.6 does not drop when the kernel switches mode. Otherwise, P0.6 goes low for the reset period. For example, if MRST is required for power-down, it can be reconfigured in GP0CON MMR.

The input level of any GPIO can be read at any time in the GPxDAT MMR, even when the pin is configured in a mode other than GPIO. The PLA input is always active.

When the ADuC7124 enters a power-saving mode, the GPIO pins retain their state. Also note that, by setting RSTCFG Bit 0, the GPIO pins can retain their state during a watchdog or software reset.

Table 79. GPIO Pin Function Descriptions

Port	Pin	Configuration			
		00	01	10	11
0	P0.0/BM	GPIO	CMP	MS0	PLAI[7]

	P4.6	GPIO		AD14	PLAO[14]
	P4.7	GPIO		AD15	PLAO[15]

¹ These pins should not be used by user code.

² When configured in Mode 1, P0.7 is ECLK by default, or core clock output. To configure it as a clock input, the MDCLK bits in PLLCON must be set to 11.

³ The CONV_{START} signal is active in all modes of P2.0.

ADuC7124

Table 80. GPxCON Registers

Name	Address	Default Value	Access
GP0CON	0xFFFFF400	0x00000000	R/W
GP1CON	0xFFFFF404	0x00000000	R/W
GP2CON	0xFFFFF408	0x00000000	R/W
GP3CON	0xFFFFF40C	0x00000000	R/W
GP4CON	0xFFFFF410	0x00000000	R/W

GPxCON are the Port x control registers, which select the function of each pin of Port x as described in Table 81.

Table 81. GPxCON MMR Bit Descriptions

Bit	Description
31:30	Reserved.
29:28	Select function of Px.7 pin.
27:26	Reserved.
25:24	Select function of Px.6 pin.
23:22	Reserved.
21:20	Select function of Px.5 pin.
19:18	Reserved.
17:16	Select function of Px.4 pin.
15:14	Reserved.
13:12	Select function of Px.3 pin.
11:10	Reserved.
9:8	Select function of Px.2 pin.
7:6	Reserved.
5:4	Select function of Px.1 pin.
3:2	Reserved.
1:0	Select function of Px.0 pin.

Table 82. GPxPAR Registers

Name	Address	Default Value	Access
GP0PAR	0xFFFFF42C	0x20000000	R/W
GP1PAR	0xFFFFF43C	0x00000000	R/W
GP2PAR	0xFFFFF44C	0x00000000	R/W
GP3PAR	0xFFFFF45C	0x00000000	R/W
GP4PAR	0xFFFFF46C	0x00000000	R/W

The GPxPAR registers program the parameters for Port 0/ Port 1/Port 2/Port 3/Port 4. Note that the GPxDAT MMR must always be written after changing the GPxPAR MMR.

Table 83. GPxPAR MMR Bit Descriptions

Bit	Description
31	Reserved.

28	Pull-up disable Px.7.
27	Reserved.
26:25	Drive strength Px.6
24	Pull-up disable Px.6.
23	Reserved.
22:21	Drive strength Px.5
20	Pull-up disable Px.5.
19	Reserved.
18:17	Drive strength Px.4
16	Pull-up disable Px.4.

Bit	Description
15	Reserved.
14:13	Drive strength Px.3
12	Pull-up disable Px.3.
11	Reserved.
10:9	Drive strength Px.2
8	Pull-up disable Px.2.
7	Reserved.
6:5	Drive strength Px.1
4	Pull-up disable Px.1.
3	Reserved.
2:1	Drive strength Px.0
0	Pull-up disable Px.0.

Table 84. GPIO Drive Strength Control Bits Descriptions

Control Bits Value	Description
00	Medium drive strength.
01	Low drive strength.
1x	High drive strength.

Figure 45. Programmable Strength for High Level

Figure 46. Programmable Strength for Low Level

The drive strength bits can be written only once after reset. More writing to related bits has no effect on changing drive strength. The GPIO drive strength and pull-up disable are not always adjustable for GPIO port. Some control bits cannot be changed. See details from Table 82.

Table 85. GPxDAT Registers

Name	Address	Default Value	Access
GP0DAT	0xFFFFF420	0x000000XX	R/W
GP1DAT	0xFFFFF430	0x000000XX	R/W
GP2DAT	0xFFFFF440	0x000000XX	R/W
GP3DAT	0xFFFFF450	0x000000XX	R/W
GP4DAT	0xFFFFF460	0x000000XX	R/W

The GPxDAT are Port x configuration and data registers. They configure the direction of the GPIO pins of Port x, set the output value for the pins configured as output, and store the input value of the pins configured as input.

Table 86. GPxDAT MMR Bit Descriptions

Bit	Description
31:24	Direction of the data. Set to 1 by the user to configure the GPIO pin as an output. Cleared to 0 by the user to configure the GPIO pin as an input.
23:16	Port x data output.
15:8	Reflect the state of Port x pins at reset (read only).
7:0	Port x data input (read only).

Table 87. GPxSET Registers

Name	Address	Default Value	Access
GP0SET	0xFFFFF424	0x000000XX	W
GP1SET	0xFFFFF434	0x000000XX	W
GP2SET	0xFFFFF444	0x000000XX	W
GP3SET	0xFFFFF454	0x000000XX	W
GP4SET	0xFFFFF464	0x000000XX	W

The GPxSET are data set Port x registers.

Table 88. GPxSET MMR Bit Descriptions

Bit	Description
31:24	Reserved.
23:16	Data Port x set bit. Set to 1 by the user to set a bit on Port x; also sets the corresponding bit in the GPxDAT MMR. Cleared to 0 by the user; does not affect the data out.
15:0	Reserved.

Table 89. GPxCLR Registers

Name	Address	Default Value	Access
GP0CLR	0xFFFFF428	0x000000XX	W
GP1CLR	0xFFFFF438	0x000000XX	W
GP2CLR	0xFFFFF448	0x000000XX	W
GP3CLR	0xFFFFF458	0x000000XX	W
GP4CLR	0xFFFFF468	0x000000XX	W

The GPxCLR are data clear Port x registers.

Table 90. GPxCLR MMR Bit Descriptions

Bit	Description
31:24	Reserved.
23:16	Data Port x clear bit. Set to 1 by the user to clear a bit on Port x; also clears the corresponding bit in the GPxDAT MMR. Cleared to 0 by the user; does not affect the data out.
15:0	Reserved.

SERIAL PORT MUX

The serial port mux multiplexes the serial port peripherals (an SPI, UART, and two I²Cs) and the programmable logic array (PLA) to a set of 10 GPIO pins. Each pin must be configured to one of its specific I/O functions as described in Table 91.

Table 91. SPM Configuration

SPMMUX	GPIO (00)	UART (01)	UART/I ² C/SPI (10)	PLA (11)
SPM0	P1.0	SIN0	I2C0SCL	PLAI[0]
SPM1	P1.1	SOUT0	I2C0SDA	PLAI[1]
SPM2	P1.2	RTS	I2C1SCL	PLAI[2]
SPM3	P1.3	CTS	I2C1SDA	PLAI[3]
SPM4	P1.4	RI	SPICLK	PLAI[4]
SPM5	P1.5	DCD	SPIMISO	PLAI[5]
SPM6	P1.6	DSR	SPIMOSI	PLAI[6]
SPM7	P1.7	DTR	SPI \overline{CS}	PLAO[0]
SPM8	P0.7	ECLK/XCLK	SIN0	PLAO[4]
SPM9	P2.0	CONV	SOUT0	PLAO[5]

Table 91 also details the mode for each of the SPMMUX pins. This configuration has to be done via the GP0CON, GP1CON, and GP2CON MMRs. By default, these 10 pins are configured as GPIOs.

UART SERIAL INTERFACE

The UART peripheral is a full-duplex, universal, asynchronous receiver/transmitter. The UART performs serial-to-parallel conversions on data characters received from a peripheral device and parallel-to-serial conversions on data characters received from the CPU. The ADuC7124 has been equipped with two industry standard 16,450 type UARTs (UART0 and UART1). Each UART features a fractional divider that facilitates high accuracy baud rate generation and is equipped with a 16-byte FIFO for the transmitter and a 16-byte FIFO for the receiver. Both UARTs can be configured as FIFO mode and non-FIFO mode.

The serial communication adopts an asynchronous protocol, which supports various word lengths, stop bits, and parity generation options selectable in the configuration register.

Baud Rate Generation

There are two ways of generating the UART baud rate, using normal 450 UART baud rate generation and using the fractional divider.

ADuC7124

Normal 450 UART Baud Rate Generation

The baud rate is a divided version of the core clock using the value in the COMDIV0 and COMDIV1 MMRs (16-bit value, DL).

$$\text{Baud Rate} = \frac{41.78 \text{ MHz}}{2^{CD} \times 16 \times 2 \times DL}$$

Table 92 gives some common baud rate values.

Table 92. Baud Rate Using the Normal Baud Rate Generator

Baud Rate	CD	DL	Actual Baud Rate	% Error
9600	0	0x88	9600	0
19,200	0	0x44	19,200	0
115,200	0	0x0B	118,691	3
9600	3	0x11	9600	0
19,200	3	0x08	20,400	6.25
115,200	3	0x01	163,200	41.67

The Fractional Divider

The fractional divider, combined with the normal baud rate generator, produces a wider range of more accurate baud rates.

Figure 47. Baud Rate Generation Options

Calculation of the baud rate using fractional divider is as follows:

$$\text{Baud Rate} = \frac{41.78 \text{ MHz}}{2^{CD} \times 16 \times DL \times 2 \times \left(M + \frac{N}{2048} \right)}$$

$$M + \frac{N}{2048} = \frac{41.78 \text{ MHz}}{\text{Baud Rate} \times 2^{CD} \times 16 \times DL \times 2}$$

For example, generation of 19,200 baud with CD bits = 3 (Table 92 gives DL = 0x08) is

$$M + \frac{N}{2048} = \frac{41.78 \text{ MHz}}{19,200 \times 2^3 \times 16 \times 8 \times 2}$$

$$M + \frac{N}{2048} = 1.06$$

where:

$$M = 1.$$

$$N = 0.06 \times 2048 = 128.$$

$$\text{Baud Rate} = \frac{41.78 \text{ MHz}}{2^3 \times 16 \times 8 \times 2 \times \left(\frac{128}{2048} \right)}$$

where:

$$\text{Baud Rate} = 19,200 \text{ bps.}$$

Error = 0%, compared to 6.25% with the normal baud rate generator.

UART Register Definitions

COM0TX Register

Name:	COM0TX
Address:	0xFFFF0700
Default Value:	0x00
Access:	Read/write

COM0TX is an 8-bit transmit register for UART0.

COM1TX Register

Name:	COM1TX
Address:	0xFFFF0740
Default Value:	0x00
Access:	Read/write

COM1TX is an 8-bit transmit register for UART1.

COM0RX Register

Name:	COM0RX
Address:	0xFFFF0700
Default Value:	0x00
Access:	Read only

COM0RX is an 8-bit receive register for UART0.

COM1RX Register

Name:	COM1RX
Address:	0xFFFF0740
Default Value:	0x00
Access:	Read only

COM1RX is an 8-bit receive register for UART1.

COM0DIV0 Register

Name:	COM0DIV0
Address:	0xFFFF0700
Default Value:	0x00
Access:	Read/write

COM0DIV0 is a low byte divisor latch for UART0. COM0TX, COM0RX, and COM0DIV0 share the same address location. COM0TX and COM0RX can be accessed when Bit 7 in the COM0CON0 register is cleared. COM0DIV0 can be accessed when Bit 7 of COM0CON0 is set.

COM1DIV0 Register

Name: COM1DIV0
 Address: 0xFFFF0740
 Default Value: 0x00
 Access: Read/write

COM1DIV0 is a low byte divisor latch for UART1. COM1TX, COM1RX, and COM1DIV0 share the same address location. COM1TX and COM1RX can be accessed when Bit 7 in COM1CON0 register is cleared. COM1DIV0 can be accessed when Bit 7 of COM1CON0 is set.

COM0IEN0 Register

Name: COM0IEN0
 Address: 0xFFFF0704
 Default Value: 0x00
 Access: Read/write

COM0IEN0 is the interrupt enable register for UART0.

COM1IEN0 Register

Name: COM1IEN0
 Address: 0xFFFF0744
 Default Value: 0x00
 Access: Read/write

COM1IEN0 is the interrupt enable register for UART1.

Table 93. COMxIEN0 MMR Bit Descriptions

Bit	Name	Description
7:4		Reserved.
3	EDSSI	Modem status interrupt enable bit. Set by the user to enable generation of an interrupt if any of COMXSTA1[3:1] are set. Cleared by the user.
2	ELSI	Rx status interrupt enable bit. Set by the user to enable generation of an interrupt if any of COMxSTA0[3:0] are set. Cleared by the user.
1	ETBEI	Enable transmit buffer empty interrupt. Set by the user to enable interrupt when buffer is empty during a transmission. Cleared by the user.
0	ERBFI	Enable receive buffer full interrupt. In non-FIFO mode, set by the user to enable interrupt when buffer is full during a reception. Cleared by the user. In FIFO mode, set by the user to enable interrupt when trigger level is reached. It also controls the character receive time-out interrupt. Cleared by the user.

COM0DIV1 Register

Name: COM0DIV1
 Address: 0xFFFF0704
 Default Value: 0x00
 Access: Read/write

COM0DIV1 is a divisor latch (high byte) register for UART0.

COM1DIV1 Register

Name: COM1DIV1
 Address: 0xFFFF0744
 Default Value: 0x00
 Access: Read/write

COM1DIV1 is a divisor latch (high byte) register for UART1.

COM0IID0 Register

Name: COM0IID0
 Address: 0xFFFF0708
 Default Value: 0x01
 Access: Read only

COM0IID0 is the interrupt identification register for UART0. It also indicates if the UART is at FIFO mode.

COM1IID0 Register

Name: COM1IID0
 Address: 0xFFFF0748
 Default Value: 0x01
 Access: Read only

COM1IID0 is the interrupt identification register for UART1. It also indicates if the UART is at FIFO mode.

Table 94. COMxIID0 MMR Bit Descriptions

Bit	Name	Description
7:6	FIFOMODE	FIFO mode flag. 0x0: non-FIFO mode. 0x1: reserved. 0x2: reserved. 0x3: FIFO mode. Set automatically if FIFOEN is set.
5:4	Reserved	
3:1	STATUS[2:0]	Interrupt status bits that work only when NINT is set. [000]: modem status interrupt. Cleared by reading COMxSTA1. Priority 4. [001]: for non-FIFO mode, transmit buffer empty interrupt. For FIFO mode, TXFIFO is empty. Cleared by writing COMxTX or reading COMxIID0. Priority 3. [010]: non-FIFO mode. Receive buffer data ready interrupt. Cleared automatically by reading COMxRX. For FIFO mode, set trigger level reached. Cleared automatically when FIFO drops below the trigger level. Priority 2. [011]: receive line status error interrupt. Cleared by reading COMxSTA0. Priority 1. [110]: RXFIFO timeout interrupt (FIFO mode only). Set automatically if there is at least one byte in RXFIFO, and there is no access to RXFIFO in the next four-frames accessing cycle. Cleared by read COMxRX, set RXRST or when a new byte arrives in RXFIFO ¹ . Priority 2. [Other state]: reserved.
0	NINT	Set to disable interrupt flags by STATUS. Clear to enable interrupt.

¹ A frame time is the time allotted for one start bit, n data bits, one parity bit, and one stop bit. Here, n is the word length selected with the WLS bits in COMxCON0.

WLS[1:0] = 00: timeout threshold = time for 32 bits = (1 + 5 + 1 + 1) × 4.

WLS[1:0] = 01: timeout threshold = time for 36 bits = (1 + 6 + 1 + 1) × 4.

WLS[1:0] = 10: timeout threshold = time for 40 bits = (1 + 7 + 1 + 1) × 4.

WLS[1:0] = 11: timeout threshold = time for 44 bits = (1 + 8 + 1 + 1) × 4.

COM0FCR Register

Name: COM0FCR

Address: 0xFFFF0708

Default Value: 0x00

Access: Write only

The FIFO control register (FCR) is a write-only register at the same address as the interrupt identification register (IIR), which is a read-only register.

COM1FCR Register

Name: COM1FCR

Address: 0xFFFF0748

Default Value: 0x00

Access: Write only

The FIFO control register (FCR) is a write-only register at the same address as the interrupt identification register (IIR), which is a read-only register.

Table 95. COMxFCR MMR Bit Descriptions

Bit	Name	Description
7:5	RXFIFOTL	Receiver FIFO trigger level. RXFIFOTL sets the trigger level for the receiver FIFO. When the trigger level is reached, a receiver data-ready interrupt is generated (if the interrupt request is enabled). Once the FIFO drops below the trigger level, the interrupt is cleared. 0x0: one byte. 0x1: two bytes. 0x2: four bytes. 0x3: six bytes. 0x4: eight bytes. 0x5: 10 bytes. 0x6: 12 bytes. 0x7: 14 bytes.
4:3	Reserved	
2	TXRST	TXFIFO reset. Writing a 1 flushes the TXFIFO. Does not affect shift register. Note that TXRST should be cleared manually to make TXFIFO work after flushing.
1	RXRST	RXFIFO reset. Writing a 1 flushes the RXFIFO. Does not affect shift register. Note that RXRST should be cleared manually to make RXFIFO work after flushing.
0	FIFOEN	Transmitter and receiver FIFOs mode enable. FIFOEN must be set before other FCR bits are written to. Set for FIFO mode. The transmitter and receiver FIFOs are enabled. Cleared for non-FIFO mode; the transmitter and receiver FIFOs are disabled, and the FIFO pointers are cleared.

COM0CON0 Register

Name: COM0CON0

Address: 0xFFFF070C

Default Value: 0x00

Access: Read/write

COM0CON0 is the line control register for UART0.

COM1CON0 Register

Name:	COM1CON0
Address:	0xFFFF074C
Default Value:	0x00
Access:	Read/write

COM1CON0 is the line control register for UART1.

Table 96. COMxCON0 MMR Bit Descriptions

Bit	Name	Description
7	DLAB	Divisor latch access. Set by the user to enable access to the COMxDIV0 and COMxDIV1 registers. Cleared by the user to disable access to COMxDIV0 and COMxDIV1 and enable access to COMxRX and COMxTX.
6	BRK	Set break. Set by the user to force SOUT to 0. Cleared to operate in normal mode.
5	SP	Stick parity. Set by the user to force parity to defined values: 1 if EPS = 1 and PEN = 1, 0 if EPS = 0 and PEN = 1.
4	EPS	Even parity select bit. Set for even parity. Cleared for odd parity.
3	PEN	Parity enable bit. Set by the user to transmit and check the parity bit. Cleared by the user for no parity transmission or checking.
2	STOP	Stop bit. Set by the user to transmit 1.5 stop bits if the word length is five bits or two stop bits if the word length is six bits, seven bits, or eight bits. The receiver checks the first stop bit only, regardless of the number of stop bits selected. Cleared by the user to generate one stop bit in the transmitted data.
1:0	WLS	Word length select: 00 = five bits, 01 = six bits, 10 = seven bits, 11 = eight bits.

COM0CON1 Register

Name:	COM0CON1
Address:	0xFFFF0710
Default Value:	0x00
Access:	Read/write

COM0CON1 is the modem control register for UART0.

COM1CON1 Register

Name:	COM1CON1
Address:	0xFFFF0750
Default Value:	0x00
Access:	Read/write

COM1CON1 is the modem control register for UART1.

Table 97. COMxCON1 MMR Bit Descriptions

Bit	Name	Description
7:5		Reserved.
4	LOOPBACK	Loop back. Set by the user to enable loopback mode. In loop-back mode, SOUT is forced high. The modem signals are also directly connected to the status inputs (RTS to CTS and DTR to DSR). Cleared by the user to be in normal mode.
3	PEN	Parity enable bit. Set by the user to transmit and check the parity bit. Cleared by the user for no parity transmission or checking.
2	STOP	Stop bit. Set by the user to transmit 1.5 stop bits if the word length is five bits or two stop bits if the word length is six bits, seven bits, or eight bits. The receiver checks the first stop bit only, regardless of the number of stop bits selected. Cleared by the user to generate one stop bit in the transmitted data.
1	RTS	Request to send. Set by the user to force the RTS output to 0. Cleared by the user to force the RTS output to 1.
0	DTR	Data terminal ready. Set by the user to force the DTR output to 0. Cleared by the user to force the DTR output to 1.

COM0STA0 Register

Name:	COM0STA0
Address:	0xFFFF0714
Default Value:	0xE0
Access:	Read only

COM0STA0 is the line status register for UART0.

ADuC7124

COM1STA0 Register

Name: COM1STA0

Address: 0xFFFF0754

Default Value: 0xE0

Access: Read only

COM1STA0 is the line status register for UART1.

Table 98. COMxSTA0 MMR Bit Descriptions

Bit	Name	Description
11	RX_error	Set automatically if PE, FE, or BI is set. Cleared automatically when PE, FE and BI are cleared.
10	RX_timeout	Only for FIFO mode. Set automatically if there is at least one byte in RXFIFO and there is no access to RXFIFO in the next four-bytes accessing cycle.
9	RX_triggered	Only for FIFO mode. Set automatically if the RXFIFO number exceeds the trigger level, which is configured by the FIFO control register COMxFCR[7:5]. Cleared automatically when RXFIFO number is equal to or less than the trigger level.
8	TX_full	Only for FIFO mode. Set automatically if TXFIFO full. Cleared automatically when TXFIFO is not full.
7	TX_half_empty	Only for FIFO mode. Set automatically if TXFIFO is half empty (number of bytes in TXFIFO ≤ 8). Cleared automatically when TXFIFO received bytes is more than eight bytes.
6	TEMT	COMxTX empty status bit. For non-FIFO mode, both THR and TSR are empty. For FIFO mode, both TXFIFO and TSR are empty.
5	THRE	COMxTX and transmitter shift register empty. For non-FIFO mode, transmitter hold register (THR) empty or the content of THR has been transferred to the transmitter shift register (TSR). For FIFO mode, TXFIFO empty, or the last character in the FIFO has been transferred to the transmitter shift register (TSR).
4	BI	Break error. Set when SIN is held low for more than the maximum word length. Cleared automatically.
3	FE	Framing error. Set when an invalid stop bit occurs. Cleared automatically.
2	PE	Parity error. Set when a parity error occurs. Cleared automatically.

Bit	Name	Description
1	OE	Overrun error. For non-FIFO mode, set automatically if data is overwritten before being read. Cleared automatically. For FIFO mode, set automatically if an overrun error has been detected. An overrun error occurs only after the FIFO is full and the next character has been completely received in the shift register. The new character overwrites the character in the shift register, but it is not transferred to the FIFO.
0	DR	Data ready. For non-FIFO mode, set automatically when COMxRX is full. Cleared by reading COMxRX. For FIFO mode, set automatically when there is at least one unread byte in the COMxRX.

COM0STA1 Register

Name: COM0STA1

Address: 0xFFFF0718

Default Value: 0x00

Access: Read only

COM0STA1 is a modem status register.

COM1STA1 Register

Name: COM1STA1

Address: 0xFFFF0758

Default Value: 0x00

Access: Read only

COM1STA1 is a modem status register.

Table 99. COMxSTA1 MMR Bit Descriptions

Bit	Name	Description
7	DCD	Data carrier detect.
6	RI	Ring indicator.
5	DSR	Data set ready.
4	CTS	Clear to send.
3	DDCD	Delta DCD. Set automatically if DCD changed state since last COMxSTA1 read. Cleared automatically by reading COMxSTA1.
2	TERI	Trailing edge RI. Set if RI changed from 0 to 1 since COMxSTA1 last read. Cleared automatically by reading COMxSTA1.
1	DDSR	Delta DSR. Set automatically if DSR changed state since COMxSTA1 last read. Cleared automatically by reading COMxSTA1.
0	DCTS	Delta CTS. Set automatically if CTS changed state since COMxSTA1 last read. Cleared automatically by reading COMxSTA1.

COM0DIV2 Register

Name:	COM0DIV2
Address:	0xFFFF072C
Default Value:	0x0000
Access:	Read/write

COM0DIV2 is a 16-bit fractional baud divide register for UART0.

COM1DIV2 Register

Name:	COM1DIV2
Address:	0xFFFF076C
Default Value:	0x0000
Access:	Read/write

COM1DIV2 is a 16-bit fractional baud divide register for UART1.

Table 100. COMxDIV2 MMR Bit Descriptions

Bit	Name	Description
15	FBEN	Fractional baud rate generator enable bit. Set by the user to enable the fractional baud rate generator. Cleared by the user to generate the baud rate using the standard 450 UART baud rate generator.
14:13		Reserved.
12:11	FBM[1:0]	M if FBM = 0, M = 4 (see The Fractional Divider section).
10:0	FBN[10:0]	N (see The Fractional Divider section).

SERIAL PERIPHERAL INTERFACE

The ADuC7124 integrates a complete hardware serial peripheral interface (SPI) on-chip. SPI is an industry standard, synchronous serial interface that allows eight bits of data to be synchronously transmitted and simultaneously received, that is, full duplex up to a maximum bit rate of 20 Mbps.

The SPI port can be configured for master or slave operation and typically consists of four pins: SPIMISO, SPIMOSI, SPICLK, and SPIC \overline{S} .

SPIMISO (Master In, Slave Out) Pin

The SPIMISO pin is configured as an input line in master mode and an output line in slave mode. The SPIMISO line on the master (data in) should be connected to the SPIMISO line in the slave device (data out). The data is transferred as byte wide (8-bit) serial data, MSB first.

SPIMOSI (Master Out, Slave In) Pin

The SPIMOSI pin is configured as an output line in master mode and an input line in slave mode. The SPIMOSI line on the master (data out) should be connected to the SPIMOSI line in

the slave device (data in). The data is transferred as byte wide (8-bit) serial data, MSB first.

SPICLK(Serial Clock I/O) Pin

The master serial clock (SPICLK) synchronizes the data being transmitted and received through the MOSI SPICLK period. Therefore, a byte is transmitted/received after eight SPICLK periods. The SPICLK pin is configured as an output in master mode and as an input in slave mode.

In master mode, polarity and phase of the clock are controlled by the SPICON register, and the bit rate is defined in the SPIDIV register as follows:

$$f_{SERIAL\ CLOCK} = \frac{f_{UCLK}}{2 \times (1 + SPIDIV)}$$

The maximum speed of the SPI clock is independent of the clock divider bits.

In slave mode, the SPICON register must be configured with the phase and polarity of the expected input clock. The slave accepts data from an external master up to 10 Mbps.

In both master and slave modes, data is transmitted on one edge of the SPICLK signal and sampled on the other. Therefore, it is important that the polarity and phase be configured the same for the master and slave devices.

SPI Chip Select (SPIC \overline{S} Input) Pin

In SPI slave mode, a transfer is initiated by the assertion of SPIC \overline{S} , which is an active low input signal. The SPI port then transmits and receives 8-bit data until the transfer is concluded by deassertion of SPIC \overline{S} . In slave mode, SPIC \overline{S} is always an input.

In SPI master mode, the SPIC \overline{S} is an active low output signal. It asserts itself automatically at the beginning of a transfer and deasserts itself upon completion.

Configuring External Pins for SPI functionality

The SPI pins of the ADuC7124 device are P1.4 to P1.7.

P1.7 is the slave chip select pin. In slave mode, this pin is an input and must be driven low by the master. In master mode, this pin is an output and goes low at the beginning of a transfer and high at the end of a transfer.

P1.4 is the SPICLK pin.

P1.5 is the master in, slave out (SPIMISO) pin.

P1.6 is the master out, slave in (SPIMOSI) pin.

To configure P1[4:7] for SPI mode, see the General-Purpose Input/Output section.

SPI Registers

The following MMR registers control the SPI interface: SPISTA, SPIRX, SPITX, SPIDIV, and SPICON.

ADuC7124

SPI Status Register

Name: SPISTA

Address: 0xFFFF0A00

Default Value: 0x0000

Access: Read/write

Function: This 32-bit MMR contains the status of the SPI interface in both master and slave modes.

Table 101. SPISTA MMR Bit Designations

Bit	Name	Description
15:12		Reserved bits.
11	SPIREX	SPI Rx FIFO excess bytes present. This bit is set when there are more bytes in the Rx FIFO than indicated in the SPIMDE bits in SPICON. This bit is cleared when the number of bytes in the FIFO is equal to or less than the number in SPIMDE.
10:8	SPIRXFSTA[2:0]	SPI Rx FIFO status bits. [000] = Rx FIFO is empty. [001] = one valid byte in the FIFO. [010] = two valid bytes in the FIFO. [011] = three valid bytes in the FIFO. [100] = four valid bytes in the FIFO.
7	SPIFOF	SPI Rx FIFO overflow status bit. Set when the Rx FIFO was already full when new data was loaded to the FIFO. This bit generates an interrupt except when SPIRFLH is set in SPICON. Cleared when the SPISTA register is read.
6	SPIRXIRQ	SPI Rx IRQ status bit. Set when a receive interrupt occurs. This bit is set when SPITMDE in SPICON is cleared and the required number of bytes has been received. Cleared when the SPISTA register is read.
5	SPITXIRQ	SPI Tx IRQ status bit. Set when a transmit interrupt occurs. This bit is set when SPITMDE in SPICON is set and the required number of bytes has been transmitted. Cleared when the SPISTA register is read.
4	SPITXUF	SPI Tx FIFO underflow. This bit is set when a transmit is initiated without any valid data in the Tx FIFO. This bit generates an interrupt except when SPITFLH is set in SPICON. Cleared when the SPISTA register is read.
3:1	SPITXFSTA[2:0]	SPI Tx FIFO status bits. [000] = Tx FIFO is empty. [001] = one valid byte in the FIFO. [010] = two valid bytes in the FIFO. [011] = three valid bytes in the FIFO. [100] = four valid bytes in the FIFO.
0	SPIISTA	SPI interrupt status bit. Set to 1 when an SPI-based interrupt occurs. Cleared after reading SPISTA.

SPIRX Register

Name: SPIRX
 Address: 0xFFFF0A04
 Default Value: 0x00
 Access: Read only
 Function: This 8-bit MMR is the SPI receive register.

SPITX Register

Name: SPITX
 Address: 0xFFFF0A08
 Default Value: 0x00
 Access: Write only
 Function: This 8-bit MMR is the SPI transmit register.

SPIDIV Register

Name: SPIDIV
 Address: 0xFFFF0A0C
 Default Value: 0x00
 Access: Write only
 Function: This 8-bit MMR is the SPI baud rate selection register.

SPICON Register

Name: SPICON
 Address: 0xFFFF0A10
 Default Value: 0x0000
 Access: Read/write
 Function: This 16-bit MMR configures the SPI peripheral in both master and slave modes.

Table 102. SPICON MMR Bit Designations

Bit	Name	Description
15:14	SPIMDE	SPI IRQ mode bits. These bits configure when the Tx/Rx interrupts occur in a transfer. [00] = Tx interrupt occurs when one byte has been transferred. Rx interrupt occurs when one or more bytes have been received into the FIFO. [01] = Tx interrupt occurs when two bytes has been transferred. Rx interrupt occurs when two or more bytes have been received into the FIFO. [10] = Tx interrupt occurs when three bytes has been transferred. Rx interrupt occurs when three or more bytes have been received into the FIFO. [11] = Tx interrupt occurs when four bytes has been transferred. Rx interrupt occurs when the Rx FIFO is full or four bytes are present.
13	SPITFLH	SPI Tx FIFO flush enable bit. Set this bit to flush the Tx FIFO. This bit does not clear itself and should be toggled if a single flush is required. If this bit is left high, then either the last transmitted value or 0x00 is transmitted, depending on the SPIZEN bit. Any writes to the Tx FIFO are ignored while this bit is set. Clear this bit to disable Tx FIFO flushing.
12	SPIRFLH	SPI Rx FIFO flush enable bit. Set this bit to flush the Rx FIFO. This bit does not clear itself and should be toggled if a single flush is required. If this bit is set incoming, data is ignored and no interrupts are generated. If set and SPITMDE = 0, a read of the Rx FIFO initiates a transfer. Clear this bit to disable Rx FIFO flushing.
11	SPICONT	Continuous transfer enable. Set by the user to enable continuous transfer. In master mode, the transfer continues until no valid data is available in the Tx register. \overline{CS} is asserted and remains asserted for the duration of each 8-bit serial transfer until Tx is empty. Cleared by the user to disable continuous transfer. Each transfer consists of a single 8-bit serial transfer. If valid data exists in the SPITX register, then a new transfer is initiated after a stall period of one serial clock cycle.
10	SPILP	Loop back enable bit. Set by the user to connect MISO to MOSI and test software. Cleared by the user to be in normal mode.
9	SPIOEN	Slave MISO output enable bit. Set this bit for MISO to operate as normal. Clear this bit to disable the output driver on the MISO pin. The MISO pin is open-drain when this bit is cleared.

ADuC7124

Bit	Name	Description
8	SPIROW	SPIRX overflow overwrite enable. Set by the user, the valid data in the Rx register is overwritten by the new serial byte received. Cleared by the user, the new serial byte received is discarded.
7	SPIZEN	SPI transmit zeros when Tx FIFO is empty. Set this bit to transmit 0x00 when there is no valid data in the Tx FIFO. Clear this bit to transmit the last transmitted value when there is no valid data in the Tx FIFO.
6	SPITMDE	SPI transfer and interrupt mode. Set by the user to initiate transfer with a write to the SPITX register. Interrupt occurs only when Tx is empty. Cleared by the user to initiate transfer with a read of the SPIRX register. Interrupt occurs only when Rx is full.
5	SPILF	LSB first transfer enable bit. Set by the user, the LSB is transmitted first. Cleared by the user, the MSB is transmitted first.
4	SPIWOM	SPI wired or mode enable bit. Set to 1 enable open drain data output. External pull-ups required on data out pins. Cleared for normal output levels.
3	SPICPO	Serial clock polarity mode bit. Set by the user, the serial clock idles high. Cleared by the user, the serial clock idles low.
2	SPICPH	Serial clock phase mode bit. Set by the user, the serial clock pulses at the beginning of each serial bit transfer. Cleared by the user, the serial clock pulses at the end of each serial bit transfer.
1	SPIMEN	Master mode enable bit. Set by the user to enable master mode. Cleared by the user to enable slave mode.
0	SPIEN	SPI enable bit. Set by the user to enable the SPI. Cleared by the user to disable the SPI.

I²C

The ADuC7124 incorporates two I²C peripherals that can be configured as a fully I²C compatible I²C bus master device or, as a fully I²C bus compatible slave device. Both I²C channels are identical. Therefore, the following descriptions apply to both channels.

The two pins used for data transfer, SDA and SCL, are configured in a wired AND format that allows arbitration in a multimaster system. These pins require external pull-up resistors. Typical pull-up values are between 4.7 k Ω and 10 k Ω .

The I²C bus peripheral address in the I²C bus system is programmed by the user. This ID can be modified any time a transfer is not in progress. The user can configure the interface to respond to four slave addresses.

The transfer sequence of an I²C system consists of a master device initiating a transfer by generating a start condition while the bus is idle. The master transmits the slave device address and the direction of the data transfer (read or/write) during the initial address transfer. If the master does not lose arbitration and the slave acknowledges, the data transfer is initiated. This continues until the master issues a stop condition and the bus becomes idle.

The I²C peripheral can only be configured as a master or slave at any given time. The same I²C channel cannot simultaneously support master and slave modes.

The I²C interface on the ADuC7124 includes the following features:

- Support for repeated start conditions. In master mode, the ADuC7124 can be programmed to generate a repeated start. In slave mode, the ADuC7124 recognizes repeated start conditions.
- In master and slave mode, the part recognizes both 7-bit and 10-bit bus addresses.
- In I²C master mode, the ADuC7124 supports continuous reads from a single slave up to 512 bytes in a single transfer sequence.
- Clock stretching is supported in both master and slave modes.
- In slave mode, the ADuC7124 can be programmed to return a NACK. This allows the validation of checksum bytes at the end of I²C transfers.
- Bus arbitration in master mode is supported.
- Internal and external loopback modes are supported for I²C hardware testing in loopback mode.
- The transmit and receive circuits in both master and slave mode contain 2-byte FIFOs. Status bits are available to the user to control these FIFOs.

Configuring External Pins for I²C Functionality

The I²C pins of the ADuC7124 device are P1.0 and P1.1 for I2C0 and P1.2 and P1.3 for I2C1.

P1.0 and P1.2 are the I²C clock signals, and P1.1 and P1.3 are the I²C data signals. For instance, to configure I2C0 pins (SCL0, SDA0), Bit 0 and Bit 4 of the GP1CON register must be set to 1 to enable I²C mode. On the other hand, to configure I2C1 pins (SCL1, SDA1), Bit 8 and Bit 12 of the GP1CON register must be set to 1 to enable I²C mode, as shown in the General-Purpose Input/Output section.

Serial Clock Generation

The I²C master in the system generates the serial clock for a transfer. The master channel can be configured to operate in fast mode (400 kHz) or standard mode (100 kHz).

The bit rate is defined in the I2CxDIV MMR as follows:

$$f_{SERIAL\ CLOCK} = \frac{f_{UCLK}}{(2 + DIVH) + (2 + DIVL)}$$

where:

f_{UCLK} is the clock before the clock divider.

$DIVH$ is the high period of the clock.

$DIVL$ is the low period of the clock.

Therefore, for 100 kHz operation,

$$DIVH = DIVL = 0xCF$$

and for 400 kHz

$$DIVH = 0x28, DIVL = 0x3C$$

The I2CxDIV register corresponds to DIVH:DIVL.

I²C Bus Addresses

Slave Mode

In slave mode, the I2CxID0, I2CxID1, I2CxID2, and I2CxID3 registers contain the device IDs. The device compares the four I2CxIDx registers to the address byte received from the bus master. To be correctly addressed, the seven MSBs of either ID register must be identical to seven MSBs of the first received address byte. The LSB of the ID registers (the transfer direction bit) is ignored in the process of address recognition.

The ADuC7124 also supports 10-bit addressing mode. When Bit 1 of I2CxSCON (ADR10EN bit) is set to 1, one 10-bit address is supported in slave mode and is stored in the I2CxID0 and I2CxID1 registers. The 10-bit address is derived as follows:

I2CxID0[0] is the read/write bit and is not part of the I²C address.

$$I2CxID0[7:1] = \text{Address Bits}[6:0].$$

$$I2CxID1[2:0] = \text{Address Bits}[9:7].$$

I2CxID1[7:3] must be set to 11110b.

ADuC7124

Master Mode

In master mode, the I2CxADR0 register is programmed with the I²C address of the device.

In 7-bit address mode, I2CxADR0[7:1] are set to the device address. I2CxADR0[0] is the read/write bit.

In 10-bit address mode, the 10-bit address is created as follows:

I2CxADR0[7:3] must be set to 11110b.

I2CxADR0[2:1] = Address Bits[9:8].

I2CxADR1[7:0] = Address Bits[7:0].

I2CxADR0[0] is the read/write bit.

I²C Registers

The I²C peripheral interfaces consists of a number of MMRs. These are described in the I²C Master Registers section.

I²C Master Registers

I²C Master Control Register

Name: I2C0MCON, I2C1MCON

Address: 0xFFFF0800, 0xFFFF0900

Default Value: 0x0000, 0x0000

Access: Read/write

Function: This 16-bit MMR configures the I²C peripheral in master mode.

Table 103. I2CxMCON MMR Bit Designations

Bit	Name	Description
15:9		Reserved. These bits are reserved and should not be written to.
8	I2CMCENI	I ² C transmission complete interrupt enable bit. Set this bit to enable an interrupt on detecting a stop condition on the I ² C bus. Clear this bit to clear the interrupt source.
7	I2CNACKENI	I ² C NACK received interrupt enable bit. Set this bit to enable interrupts when the I ² C master receives a NACK. Clear this bit to clear the interrupt source.
6	I2CALENI	I ² C arbitration lost interrupt enable bit. Set this bit to enable interrupts when the I ² C master is unable to gain control of the I ² C bus. Clear this bit to clear the interrupt source.
5	I2CMTENI	I ² C transmit interrupt enable bit. Set this bit to enable interrupts when the I ² C master has transmitted a byte. Clear this bit to clear the interrupt source.
4	I2CMRENI	I ² C receive interrupt enable bit. Set this bit to enable interrupts when the I ² C master receives data. Cleared by user to disable interrupts when the I ² C master is receiving data.
3	I2CMSEN	I ² C master SCL stretch enable bit. Set this bit to 1 to enable clock stretching. When SCL is low, setting this bit forces the device to hold SCL low until I2CMSEN is cleared. If SCL is high, setting this bit forces the device to hold SCL low after the next falling edge. Clear this bit to disable clock stretching.
2	I2CILEN	I ² C internal loopback enable. Set this bit to enable loopback test mode. In this mode, the SCL and SDA signals are connected internally to their respective input signals. Cleared by the user to disable loopback mode.
1	I2CBD	I ² C master backoff disable bit Set this bit to allow the device to compete for control of the bus even if another device is currently driving a start condition. Clear this bit to wait until the I ² C bus becomes free.
0	I2CMEN	I ² C master enable bit. Set by the user to enable I ² C master mode. Clear this bit to disable I ² C master mode.

I²C Master Status Register

Name: I2C0MSTA, I2C1MSTA
Address: 0xFFFF0804, 0xFFFF0904
Default Value: 0x0000, 0x0000
Access: Read only
Function: This 16-bit MMR is the I²C status register in master mode.

Table 104 I2CxMSTA MMR Bit Designations

Bit	Name	Description
15:11		Reserved. These bits are reserved.
10	I2CBBUSY	I ² C bus busy status bit. This bit is set to 1 when a start condition is detected on the I ² C bus. This bit is cleared when a stop condition is detected on the bus.
9	I2CMRxFO	Master Rx FIFO overflow. This bit is set to 1 when a byte is written to the Rx FIFO when it is already full. This bit is cleared in all other conditions.
8	I2CMTC	I ² C transmission complete status bit. This bit is set to 1 when a transmission is complete between the master and the slave it was communicating with. If the I2CMCENI bit in I2CxMCON is set, an interrupt is generated when this bit is set. Clear this bit to clear the interrupt source.
7	I2CMNA	I ² C master NACK data bit. This bit is set to 1 when a NACK condition is received by the master in response to a data write transfer. If the I2CNACKENI bit in I2CxMCON is set, an interrupt is generated when this bit is set. This bit is cleared in all other conditions.
6	I2CMBUSY	I ² C master busy status bit. Set to 1 when the master is busy processing a transaction. Cleared if the master is ready or if another master device has control of the bus.
5	I2CAL	I ² C arbitration lost status bit. This bit is set to 1 when the I ² C master is unable to gain control of the I ² C bus. If the I2CALENI bit in I2CxMCON is set, an interrupt is generated when this bit is set. This bit is cleared in all other conditions.
4	I2CMNA	I ² C master NACK address bit. This bit is set to 1 when a NACK condition is received by the master in response to an address. If the I2CNACKENI bit in I2CxMCON is set, an interrupt is generated when this bit is set. This bit is cleared in all other conditions.
3	I2CMRXQ	I ² C master receive request bit. This bit is set to 1 when data enters the Rx FIFO. If the I2CMRENI in I2CxMCON is set, an interrupt is generated. This bit is cleared in all other conditions.
2	I2CMTXQ	I ² C master transmit request bit. This bit goes high if the Tx FIFO is empty or contains only one byte and the master has transmitted an Address + write. If the I2CMTENI bit in I2CxMCON is set, an interrupt is generated when this bit is set. This bit is cleared in all other conditions.
1-0	I2CMTFSTA	I ² C master Tx FIFO status bits. 00 = I ² C master Tx FIFO empty. 01 = one byte in master Tx FIFO. 10 = one byte in master Tx FIFO. 11 = I ² C master Tx FIFO full.

ADuC7124

I²C Master Receive Register

Name: I2C0MRX, I2C1MRX
 Address: 0xFFFF0808, 0xFFFF0908
 Default Value: 0x00
 Access: Read only
 Function: This 8-bit MMR is the I²C master receive register.

I²C Master Transmit Register

Name: I2C0MTX, I2C1MTX
 Address: 0xFFFF080C, 0xFFFF090C
 Default Value: 0x00, 0x00
 Access: Write only
 Function: This 8-bit MMR is the I²C master transmit register.

I²C Master Read Count Register

Name: I2C0MCNT0, I2C1MCNT0
 Address: 0xFFFF0810, 0xFFFF0910
 Default Value: 0x0000, 0x0000
 Access: Read/write
 Function: This 16-bit MMR holds the required number of bytes when the master begins a read sequence from a slave device.

Table 105. I2CxMCNT0 MMR Bit Descriptions (Address = 0xFFFF0810, 0xFFFF0910. Default Value = 0x0000)

Bit	Name	Description
15:9		Reserved.
8	I2CRECNT	Set this bit if greater than 256 bytes are required from the slave. Clear this bit when reading 256 bytes or less.
7:0	I2CRCNT	These eight bits hold the number of bytes required during a slave read sequence, minus 1. If only a single byte is required, these bits should be set to 0.

I²C Master Current Read Count Register

Name: I2C0MCNT1, I2C1MCNT1
 Address: 0xFFFF0814, 0xFFFF0914
 Default Value: 0x00, 0x00
 Access: Read only
 Function: This 8-bit MMR holds the number of bytes received so far during a read sequence with a slave device.

I²C Address 0 Register

Name: I2C0ADR0, I2C1ADR0
 Address: 0xFFFF0818, 0xFFFF0918
 Default Value: 0x00
 Access: Read/write
 Function: This 8-bit MMR holds the 7-bit slave address + the read/write bit when the master begins communicating with a slave.

Table 106. I2CxADR0 MMR in 7-Bit Address Mode (Address = 0xFFFF0818, 0xFFFF0918. Default Value = 0x00)

Bit	Name	Description
7:1	I2CADR	These bits contain the 7-bit address of the required slave device.
0	R/W	Bit 0 is the read/write bit. When this bit = 1, a read sequence is requested. When this bit = 0, a write sequence is requested.

Table 107. I2CxADR0 MMR in 10-Bit Address Mode

Bit	Name	Description
7:3		These bits must be set to [11110b] in 10-bit address mode.
2:1	I2CMADR	These bits contain ADDR[9:8] in 10-bit addressing mode.
0	R/W	Read/write bit. When this bit = 1, a read sequence is requested. When this bit = 0, a write sequence is requested.

I²C Address 1 Register

Name: I2C0ADR1, I2C1ADR1
 Address: 0xFFFF081C, 0xFFFF091C
 Default Value: 0x00
 Access: Read/write
 Function: This 8-bit MMR is used in 10-bit addressing mode only. This register contains the least significant byte of the address.

Table 108. I2CxADR1 MMR in 10-Bit Address Mode

Bit	Name	Description
7:0	I2CLADR	These bits contain ADDR[7:0] in 10-bit addressing mode.

I²C Master Clock Control Register

Name: I2C0DIV, I2C1DIV

Address: 0xFFFF0824, 0xFFFF0924

Default Value: 0x1F1F

Access: Read/write

Function: This MMR controls the frequency of the I²C clock generated by the master on to the SCL pin. For further details, see the I²C section.

Table 109. I2CxDIV MMR

Bit	Name	Description
15:8	DIVH	These bits control the duration of the high period of SCL.
7:0	DIVL	These bits control the duration of the low period of SCL.

I²C Slave Registers**I²C Slave Control Register**

Name: I2C0SCON, I2C1SCON

Address: 0xFFFF0828, 0xFFFF0928

Default value: 0x0000

Access: Read/write

Function: This 16-bit MMR configures the I²C peripheral in slave mode.

Table 110. I2CxSCON MMR Bit Designations

Bit	Name	Description
15:11		Reserved bits.
10	I2CSTXENI	Slave transmit interrupt enable bit. Set this bit to enable an interrupt after a slave transmits a byte. Clear this interrupt source.
9	I2CSRXENI	Slave receive interrupt enable bit. Set this bit to enable an interrupt after the slave receives data. Clear this interrupt source.
8	I2CSSENI	I ² C stop condition detected interrupt enable bit. Set this bit to enable an interrupt on detecting a stop condition on the I ² C bus. Clear this interrupt source.
7	I2CNACKEN	I ² C NACK enable bit. Set this bit to NACK the next byte in the transmission sequence. Clear this bit to let the hardware control the ACK/NACK sequence.
6	I2CSSEN	I ² C slave SCL stretch enable bit. Set this bit to 1 to enable clock stretching. When SCL is low, setting this bit forces the device to hold SCL low until I2CSSEN is cleared. If SCL is high, setting this bit forces the device to hold SCL low after the next falling edge. Clear this bit to disable clock stretching.
5	I2CSETEN	I ² C early transmit interrupt enable bit. Setting this bit enables a transmit request interrupt just after the positive edge of SCL during the read bit transmission. Clear this bit to enable a transmit request interrupt just after the negative edge of SCL during the read bit transmission.
4	I2CGCLR	I ² C general call status and ID clear bit. Writing a 1 to this bit clears the general call status and ID bits in the I2CxSSTA register. Clear this bit at all other times.

ADuC7124

Bit	Name	Description
3	I2CHGCEN	<p>I²C hardware general call enable.</p> <p>When this bit and Bit 2 are set, and having received a general call (Address 0x00) and a data byte, the device checks the contents of the I2CxALT against the receive register. If the contents match, the device has received a hardware general call. This is used if a device needs urgent attention from a master device without knowing which master it needs to turn to. This is a “to whom it may concern” call. The ADuC7124 watches for these addresses. The device that requires attention embeds its own address into the message. All masters listen, and the one that can handle the device contacts its slave and acts appropriately. The LSB of the I2CxALT register should always be written to 1, as per the I²C January 2000 bus specification.</p> <p>Set this bit and I2CGCEN to enable hardware general call recognition in slave mode.</p> <p>Clear this bit to disable recognition of hardware general call commands.</p>
2	I2CGCEN	<p>I²C general call enable.</p> <p>Set this bit to enable the slave device to acknowledge an I²C general call, Address 0x00 (write). The device then recognizes a data bit. If it receives a 0x06 (reset and write programmable part of the slave address by hardware) as the data byte, the I²C interface resets as per the I²C January 2000 bus specification. This command can be used to reset an entire I²C system. If it receives a 0x04 (write programmable part of the slave address by hardware) as the data byte, the general call interrupt status bit sets on any general call. The user must take corrective action by reprogramming the device address.</p> <p>Set this bit to allow the slave ACK I²C general call commands.</p> <p>Clear this bit to disable recognition of general call commands.</p>
1	ADR10EN	<p>I²C 10-bit address mode.</p> <p>Set to 1 to enable 10-bit address mode.</p> <p>Clear to 0 to enable normal address mode.</p>
0	I2CSEN	<p>I²C slave enable bit.</p> <p>Set by the user to enable I²C slave mode.</p> <p>Clear this bit to disable I²C slave mode.</p>

I²C Slave Status Registers

Name: I2C0SSTA, I2C1SSTA

Address: 0xFFFFF082C, 0xFFFFF092C

Default Value: 0x0000, 0x0000

Access: Read/write

Function: This 16-bit MMR is the I²C status register in slave mode.

Table 111. I2CxSSTA MMR Bit Designations

Bit	Name	Description
15		Reserved bit.
14	I2CSTA	<p>This bit is set to 1 if:</p> <ul style="list-style-type: none"> A start condition followed by a matching address is detected. A start byte (0x01) is received. General calls are enabled and a general call code of (0x00) is received. <p>This bit is cleared on receiving a stop condition.</p>
13	I2CREPS	<p>This bit is set to 1 if a repeated start condition is detected.</p> <p>This bit is cleared on receiving a stop condition.</p>
12:11	I2CID[1:0]	<p>I²C address matching register. These bits indicate which I2CxIDx register matches the received address.</p> <p>[00] = received address matches I2CxID0.</p> <p>[01] = received address matches I2CxID1.</p> <p>[10] = received address matches I2CxID2.</p> <p>[11] = received address matches I2CxID3.</p>
10	I2CSS	<p>I²C stop condition after start detected bit.</p> <p>This bit is set to 1 when a stop condition is detected after a previous start and matching address.</p> <p>When the I2CSSENI bit in I2CxSCON is set, an interrupt is generated.</p> <p>This bit is cleared by reading this register.</p>

Bit	Name	Description
9:8	I2CGCID[1:0]	I ² C general call ID bits. [00] = no general call received. [01] = general call reset and program address. [10] = general program address. [11] = general call matching alternative ID. Note that these bits are not cleared by a general call reset command. Clear these bits by writing a 1 to the I2CGCCLR bit in I2CxSCON.
7	I2CGC	I ² C general call status bit. This bit is set to 1 if the slave receives a general call command of any type. If the command received is a reset command, then all registers return to their default states. If the command received is a hardware general call, the Rx FIFO holds the second byte of the command and this can be compared with the I2CxALT register. Clear this bit by writing a 1 to the I2CGCCLR bit in I2CxSCON.
6	I2CSBUSY	I ² C slave busy status bit. Set to 1 when the slave receives a start condition. Cleared by hardware if <ul style="list-style-type: none"> The received address does not match any of the I2CxIDx registers. The slave device receives a stop condition. A repeated start address doesn't match any of the I2CxIDx registers.
5	I2CSNA	I ² C slave NACK data bit. This bit is set to 1 when the slave responds to a bus address with a NACK. This bit is asserted under the following conditions: <ul style="list-style-type: none"> INACK was returned because there was no data in the Tx FIFO. The I2CNACKEN bit was set in the I2CxSCON register. This bit is cleared in all other conditions.
4	I2CSRxFO	Slave Rx FIFO overflow. This bit is set to 1 when a byte is written to the Rx FIFO when it is already full. This bit is cleared in all other conditions.
3	I2CSRXQ	I ² C slave receive request bit. This bit is set to 1 when the slave Rx FIFO is not empty. This bit causes an interrupt to occur when the I2CSRXENI bit in I2CxSCON is set. The Rx FIFO must be read or flushed to clear this bit.
2	I2CSTXQ	I ² C slave transmit request bit. This bit is set to 1 when the slave receives a matching address followed by a read. If the I2CSETEN bit in I2CxSCON is = 0, this bit goes high just after the negative edge of SCL during the read bit transmission. If the I2CSETEN bit in I2CxSCON is = 1, this bit goes high just after the positive edge of SCL during the read bit transmission. This bit causes an interrupt to occur when the I2CSTXENI bit in I2CxSCON is set. This bit is cleared in all other conditions.
1	I2CSTFE	I ² C slave FIFO underflow status bit. This bit goes high if the Tx FIFO is empty when a master requests data from the slave. This bit is asserted at the rising edge of SCL during the read bit. This bit is cleared in all other conditions.
0	I2CETSTA	I ² C slave early transmit FIFO status bit. If the I2CSETEN bit in I2CxSCON is = 0, this bit goes high if the slave Tx FIFO is empty. If the I2CSETEN bit in I2CxSCON is = 1, this bit goes high just after the positive edge of SCL during the write bit transmission. This bit asserts once only for a transfer. This bit is cleared after being read.

ADuC7124

I²C Slave Receive Registers

Name: I2C0SRX, I2C1SRX
 Address: 0xFFFF0830, 0xFFFF0930
 Default Value: 0x00
 Access: Read
 Function: This 8-bit MMR is the I²C slave receive register.

I²C Slave Transmit Registers

Name: I2C0STX, I2C1STX
 Address: 0xFFFF0834, 0xFFFF0934
 Default Value: 0x00
 Access: Write
 Function: This 8-bit MMR is the I²C slave transmit register.

I²C Hardware General Call Recognition Registers

Name: I2C0ALT, I2C1ALT
 Address: 0xFFFF0838, 0xFFFF0938
 Default Value: 0x00
 Access: Read/write
 Function: This 8-bit MMR is used with hardware general calls when the I2CxSCON Bit 3 is set to 1. This register is used in cases where a master is unable to generate an address for a slave, and instead, the slave must generate the address for the master.

I²C Slave Device ID Registers

Name: I2C0IDx, I2C1IDx
 Addresses: 0xFFFF093C = I2C1ID0
 0xFFFF083C = I2C0ID0
 0xFFFF0940 = I2C1ID1
 0xFFFF0840 = I2C0ID1
 0xFFFF0944 = I2C1ID2
 0xFFFF0844 = I2C0ID2
 0xFFFF0948 = I2C1ID3
 0xFFFF0848 = I2C0ID3
 Default Value: 0x00
 Access: Read/write
 Function: These 8-bit MMRs are programmed with I²C bus IDs of the slave. See the I2C Bus Addresses section for further details.

I²C Common Registers

I²C FIFO Status Register

Name: I2C0FSTA, I2C1FSTA
 Address: 0xFFFF084C, 0xFFFF094C
 Default Value: 0x0000
 Access: Read/write
 Function: These 16-bit MMRs contain the status of the Rx/Tx FIFOs in both master and slave modes.

Table 112. I2CxFSTA MMR Bit Designations

Bit	Name	Description
15:10		Reserved bits.
9	I2CFMTX	Set this bit to 1 to flush the master Tx FIFO.
8	I2CFSTX	Set this bit to 1 to flush the slave Tx FIFO.
7:6	I2CMRXSTA	I ² C master receive FIFO status bits. [00] = FIFO empty. [01] = byte written to FIFO. [10] = one byte in FIFO. [11] = FIFO full.
5:4	I2CMTXSTA	I ² C master transmit FIFO status bits. [00] = FIFO empty. [01] = byte written to FIFO. [10] = one byte in FIFO. [11] = FIFO full.
3:2	I2CSRSTA	I ² C slave receive FIFO status bits. [00] = FIFO empty. [01] = byte written to FIFO. [10] = one byte in FIFO. [11] = FIFO full.
1:0	I2CSTXSTA	I ² C slave transmit FIFO status bits. [00] = FIFO empty. [01] = byte written to FIFO. [10] = one byte in FIFO. [11] = FIFO full.

PWM GENERAL OVERVIEW

The ADuC7124 integrates a six channel PWM interface (PWM0 to PWM5). The PWM outputs can be configured to drive an H-bridge or can be used as standard PWM outputs. On power-up, the PWM outputs default to H-bridge mode. This ensures that the motor is turned off by default. In standard PWM mode, the outputs are arranged as three pairs of PWM pins. The user has control over the period of each pair of outputs and over the duty cycle of each individual output.

Table 113. PWM MMRs

Name	Function
PWMCON0	PWM control.
PWM0COM0	Compare Register 0 for PWM Output 0 and PWM Output 1.
PWM0COM1	Compare Register 1 for PWM Output 0 and PWM Output 1.
PWM0COM2	Compare Register 2 for PWM Output 0 and PWM Output 1.
PWM0LEN	Frequency control for PWM Output 0 and PWM Output 1.
PWM1COM0	Compare Register 0 for PWM Output 2 and PWM Output 3.
PWM1COM1	Compare Register 1 for PWM Output 2 and PWM Output 3.
PWM1COM2	Compare Register 2 for PWM Output 2 and PWM Output 3.
PWM1LEN	Frequency control for PWM Output 2 and PWM Output 3.
PWM2COM0	Compare Register 0 for PWM Output 4 and Output 5
PWM2COM1	Compare Register 1 for PWM Outputs 4 and Output 5
PWM2COM2	Compare Register 2 for PWM Outputs 4 and Output 5
PWM2LEN	Frequency control for PWM Output 4 and PWM Output 5.
PWMCON1	PWM control register
PWMCLRI	PWM interrupt clear.

In all modes, the PWMxCOMx MMRs control the point at which the PWM outputs change state. An example of the first pair of PWM outputs (PWM0 and PWM1) is shown in Figure 48.

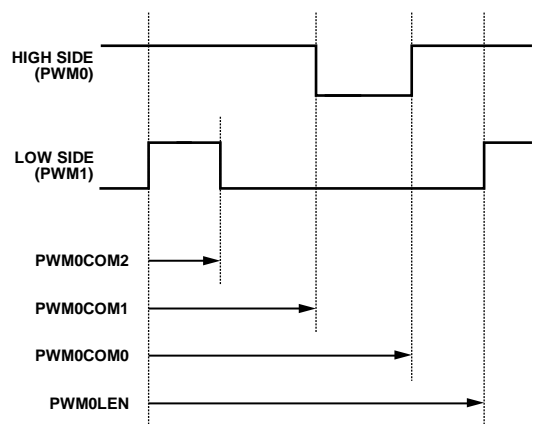

Figure 48. PWM Timing

The PWM clock is selectable via PWMCON with one of the following values: UCLK divided by 2, 4, 8, 16, 32, 64, 128, or 256. The length of a PWM period is defined by PWMxLEN.

The PWM waveforms are set by the count value of the 16-bit timer and the compare registers contents, as shown with the PWM0 and PWM1 waveforms in Figure 48.

The low-side waveform, PWM1, goes high when the timer count reaches PWM0LEN, and it goes low when the timer count reaches the value held in PWM0COM2 or when the high-side waveform (PWM0) goes low.

The high-side waveform, PWM0, goes high when the timer count reaches the value held in PWM0COM0, and it goes low when the timer count reaches the value held in PWM0COM1.

Table 114. PWMCON0 PWMCON MMR Bit Designations

Bit	Name	Description
14	SYNC	Enables PWM synchronization. Set to 1 by the user so that all PWM counters are reset on the next clock edge after the detection of a high-to-low transition on the P3.7/PWM _{SYNC} pin. Cleared by the user to ignore transitions on the P3.7/PWM _{SYNC} pin.
13	PWM5INV	Set to 1 by the user to invert PWM5. Cleared by the user to use PWM5 in normal mode.
12	PWM3INV	Set to 1 by the user to invert PWM3. Cleared by the user to use PWM3 in normal mode.
11	PWM1INV	Set to 1 by the user to invert PWM1. Cleared by the user to use PWM1 in normal mode.
10	PWMTRIP	Set to 1 by the user to enable PWM trip interrupt. When the PWM trip input (Pin P3.6/PWM _{TRIPINPUT}) is low, the PWMEN bit is cleared and an interrupt is generated. Cleared by the user to disable the PWMTRIP interrupt.
9	ENA	If HOFF = 0 and HMODE = 1; note that, if not in H-bridge mode, this bit has no effect. Set to 1 by the user to enable PWM outputs. Cleared by the user to disable PWM outputs. If HOFF = 1 and HMODE = 1, see Table 115.
8 to 6	PWMCP[2:0]	PWM clock prescaler bits. Sets the UCLK divider. [000] = UCLK/2. [001] = UCLK/4. [010] = UCLK/8. [011] = UCLK/16. [100] = UCLK/32. [101] = UCLK/64. [110] = UCLK/128. [111] = UCLK/256.
5	POINV	Set to 1 by the user to invert all PWM outputs. Cleared by the user to use PWM outputs as normal.
4	HOFF	High side off. Set to 1 by the user to force PWM0 and PWM2 outputs high. This also forces PWM1 and PWM3 low. Cleared by the user to use the PWM outputs as normal.
3	LCOMP	Load compare registers. Set to 1 by the user to load the internal compare registers with the values in PWMxCOMx on the next transition of the PWM timer from 0x00 to 0x01. Cleared by the user to use the values previously stored in the internal compare registers.
2	DIR	Direction control. Set to 1 by the user to enable PWM0 and PWM1 as the output signals while PWM2 and PWM3 are held low. Cleared by the user to enable PWM2 and PWM3 as the output signals while PWM0 and PWM1 are held low.
1	HMODE	Enables H-bridge mode. ¹ Set to 1 by the user to enable H-bridge mode and Bit 1 to Bit 5 of PWMCON. Cleared by the user to operate the PWMs in standard mode.
0	PWMEN	Set to 1 by the user to enable all PWM outputs. Cleared by the user to disable all PWM outputs.

¹ In H-bridge mode, HMODE = 1. See Table 115 to determine the PWM outputs.

Table 115. PWM Output Selection

PWMCON0 MMR ¹				PWM Outputs ²			
ENA	HOFF	POINV	DIR	PWM0	PWM1	PWM2	PWM3
0	0	X	X	1	1	1	1
X	1	X	X	1	0	1	0
1	0	0	0	0	0	HS	LS
1	0	0	1	HS	LS	0	0
1	0	1	0	HS	LS	1	1
1	0	1	1	1	1	HS	LS

¹X = don't care.

²HS = high side, LS = low side.

On power-up, PWMCON0 defaults to 0x12 (HOFF = 1 and HMODE = 1). All GPIO pins associated with the PWM are configured in PWM mode by default (see Table 116).

Table 116. Compare Registers

Name	Address	Default Value	Access
PWM0COM0	0xFFFF0F84	0x0000	R/W
PWM0COM1	0xFFFF0F88	0x0000	R/W
PWM0COM2	0xFFFF0F8C	0x0000	R/W
PWM1COM0	0xFFFF0F94	0x0000	R/W
PWM1COM1	0xFFFF0F98	0x0000	R/W
PWM1COM2	0xFFFF0F9C	0x0000	R/W
PWM2COM0	0xFFFF0FA4	0x0000	R/W
PWM2COM1	0xFFFF0FA8	0x0000	R/W
PWM2COM2	0xFFFF0FAC	0x0000	R/W

The PWM trip interrupt can be cleared by writing any value to the PWMCLR1 MMR. Note that, when using the PWM trip interrupt, users should make sure that the PWM interrupt has been cleared before exiting the ISR. This prevents generation of multiple interrupts.

PWM Convert Start Control

The PWM can be configured to generate an ADC convert start signal after the active low side signal goes high. There is a programmable delay between the time that the low-side signal goes high and the convert start signal is generated.

This is controlled via the PWMCON1 MMR. If the delay selected is higher than the width of the PWM pulse, the interrupt remains low.

Table 117. PWMCON1 MMR Bit Designations (Address = 0xFFFF0FB4. Default Value = 0x00)

Bit	Value	Name	Description
7		CSEN	Set to 1 by the user to enable the PWM to generate a convert start signal. Cleared by user to disable the PWM convert start signal.
3:0		CSD3 CSD2 CSD1 CSD0	Convert start delay. Delays the convert start signal by a number of clock pulses.
	0000		Four clock pulses.
	0001		Eight clock pulses.
	0010		12 clock pulses.
	0011		16 clock pulses.
	0100		20 clock pulses.
	0101		24 clock pulses.
	0110		28 clock pulses.
	0111		32 clock pulses.
	1000		36 clock pulses.
	1001		40 clock pulses.
	1010		44 clock pulses.
	1011		48 clock pulses.
	1100		52 clock pulses.
	1101		56 clock pulses.
	1110		60 clock pulses.
	1111		64 clock pulses.

When calculating the time from the convert start delay to the start of an ADC conversion, the user must take account of internal delays. The example below shows the case for a delay of four clocks. One additional clock is required to pass the convert start signal to the ADC logic. Once the ADC logic receives the convert start signal, an ADC conversion begins on the next ADC clock edge (see Figure 49).

Figure 49. ADC Conversion

09123-045

PROGRAMMABLE LOGIC ARRAY (PLA)

Every ADuC7124 integrates a fully programmable logic array (PLA) that consists of two independent but interconnected PLA blocks. Each block consists of eight PLA elements, giving each part a total of 16 PLA elements.

Each PLA element contains a two-input look up table that can be configured to generate any logic output function based on two inputs and a flip-flop. This is represented in Figure 50.

Figure 50. PLA Element

In total, 32 GPIO pins are available on the ADuC7124 for the PLA. These include 16 input pins and 16 output pins, which must to be configured in the GPxCON register as PLA pins before using the PLA. Note that the comparator output is also included as one of the 16 input pins.

The PLA is configured via a set of user MMRs. The output(s) of the PLA can be routed to the internal interrupt system, to the CONV_{START} signal of the ADC, to an MMR, or to any of the 16 PLA output pins.

The two blocks can be interconnected as follows:

- Output of Element 15 (Block 1) can be fed back to Input 0 of Mux 0 of Element 0 (Block 0).
- Output of Element 7 (Block 0) can be fed back to Input 0 of Mux 0 of Element 8 (Block 1).

Table 118. Element Input/Output¹

PLA Block 0			PLA Block 1		
Element	Input	Output	Element	Input	Output
0	P1.0	P1.7	8	P3.0	P4.0
1	P1.1	P0.4	9	P3.1	P4.1
2	P1.2	P0.5	10	P3.2	P4.2
3	P1.3	P0.6	11	P3.3	P4.3
4	P1.4	P0.7	12	P3.4	P4.4
5	P1.5	P2.0	13	P3.5	P4.5
6	P1.6	P2.1	14	P3.6	P4.6
7	P0.0	P2.2	15	P3.7	P4.7

¹ Not all pins in this table are connected to external pins. However, they may be routed internally via the PLA. See Table 122 for further details.

PLA MMRs Interface

The PLA peripheral interface consists of the 22 MMRs.

PLAELMx Registers

Name	Address	Default Value	Access
PLAELM0	0xFFFF0B00	0x0000	R/W
PLAELM1	0xFFFF0B04	0x0000	R/W
PLAELM2	0xFFFF0B08	0x0000	R/W
PLAELM3	0xFFFF0B0C	0x0000	R/W
PLAELM4	0xFFFF0B10	0x0000	R/W
PLAELM5	0xFFFF0B14	0x0000	R/W
PLAELM6	0xFFFF0B18	0x0000	R/W
PLAELM7	0xFFFF0B1C	0x0000	R/W
PLAELM8	0xFFFF0B20	0x0000	R/W
PLAELM9	0xFFFF0B24	0x0000	R/W
PLAELM10	0xFFFF0B28	0x0000	R/W
PLAELM11	0xFFFF0B2C	0x0000	R/W
PLAELM12	0xFFFF0B30	0x0000	R/W
PLAELM13	0xFFFF0B34	0x0000	R/W
PLAELM14	0xFFFF0B38	0x0000	R/W
PLAELM15	0xFFFF0B3C	0x0000	R/W

The PLAELMx are Element 0 to Element 15 control registers. They configure the input and output mux of each element, select the function in the look up table, and bypass/use the flip-flop (see Table 119 and Table 122).

Table 119. PLAELMx MMR Bit Descriptions

Bit	Value	Description
31:11		Reserved.
10:9		Mux 0 control (see Table 122).
8:7		Mux 1 control (see Table 122).
6		Mux 2 control. Set by the user to select the output of Mux 0. Cleared by the user to select the bit value from PLADIN.
5		Mux 3 control. Set by the user to select the input pin of the particular element. Cleared by the user to select the output of Mux 1.
4:1		Look up table control.
	0000	0.
	0001	NOR.
	0010	B AND NOT A.
	0011	NOT A.
	0100	A AND NOT B.
	0101	NOT B.
	0110	EXOR.
	0111	NAND.
	1000	AND.
	1001	EXNOR.
	1010	B.
	1011	NOT A OR B.
	1100	A.
	1101	A OR NOT B.
	1110	OR.
	1111	1.
0		Mux 4 control. Set by the user to bypass the flip-flop. Cleared by the user to select the flip-flop (cleared by default).

PLACLK Register

Name: PLACLK
 Address: 0xFFFF0B40
 Default Value: 0x00
 Access: Read/write

PLACLK is the clock selection for the flip-flops of Block 0 and Block 1. Note that the maximum frequency when using the GPIO pins as the clock input for the PLA blocks is 41.78 MHz.

Table 120. PLACLK MMR Bit Descriptions

Bit	Value	Description
7		Reserved.
6:4		Block 1 clock source selection.
	000	GPIO clock on P0.5.
	001	GPIO clock on P0.0.
	010	GPIO clock on P0.7.
	011	HCLK.
	100	OCLK (32.768 kHz).
	101	Timer1 overflow.
	110	UCLK.
	111	Internal 32,768 oscillator.
3		Reserved.
2:0		Block 0 clock source selection.
	000	GPIO clock on P0.5.
	001	GPIO clock on P0.0.
	010	GPIO clock on P0.7.
	011	HCLK.
	100	OCLK (32.768 kHz).
	101	Timer1 overflow.
	Other	Reserved.

PLAIRQ Register

Name: PLAIRQ
 Address: 0xFFFF0B44
 Default Value: 0x00000000
 Access: Read/write

PLAIRQ enables IRQ0 and/or IRQ1 and selects the source of the IRQ.

Table 121. PLAIRQ MMR Bit Descriptions

Bit	Value	Description
15:13		Reserved.
12		PLA IRQ1 enable bit. Set by the user to enable IRQ1 output from PLA. Cleared by the user to disable IRQ1 output from PLA.
11:8		PLA IRQ1 source.
	0000	PLA Element 0.
	0001	PLA Element 1.
	1111	PLA Element 15.
7:5		Reserved.
4		PLA IRQ0 enable bit. Set by the user to enable IRQ0 output from PLA. Cleared by the user to disable IRQ0 output from PLA.
3:0		PLA IRQ0 source.
	0000	PLA Element 0.
	0001	PLA Element 1.
	1111	PLA Element 15.

Table 122. Feedback Configuration

Bit	Value	PLAELM0	PLAELM1 to PLAELM7	PLAELM8	PLAELM9 to PLAELM15
10:9	00	Element 15	Element 0	Element 7	Element 8
	01	Element 2	Element 2	Element 10	Element 10
	10	Element 4	Element 4	Element 12	Element 12
	11	Element 6	Element 6	Element 14	Element 14

	11	Element 7	Element 7	Element 15	Element 15

ADuC7124

PLAADC Register

Name: PLAADC
Address: 0xFFFF0B48
Default Value: 0x00000000
Access: Read/write

PLAADC is the PLA source for the ADC start conversion signal.

Table 123. PLAADC MMR Bit Descriptions

Bit	Value	Description
31:5		Reserved.
4		ADC start conversion enable bit. Set by the user to enable ADC start conversion from PLA. Cleared by the user to disable ADC start conversion from PLA.
3:0		ADC start conversion source.
	0000	PLA Element 0.
	0001	PLA Element 1.
	1111	PLA Element 15.

PLADIN Register

Name: PLADIN
Address: 0xFFFF0B4C
Default Value: 0x00000000
Access: Read/write

PLADIN is a data input MMR for PLA.

Table 124. PLADIN MMR Bit Descriptions

Bit	Description
31:16	Reserved.
15:0	Input bit to Element 15 to Element 0.

PLADOUT Register

Name: PLADOUT
Address: 0xFFFF0B50
Default Value: 0x00000000
Access: Read only

PLADOUT is a data output MMR for PLA. This register is always updated.

Table 125. PLADOUT MMR Bit Descriptions

Bit	Description
31:16	Reserved.
15:0	Output bit from Element 15 to Element 0.

PLALCK Register

Name: PLALCK
Address: 0xFFFF0B54
Default Value: 0x00
Access: Write only

PLALCK is a PLA lock option. Bit 0 is written only once. When set, it does not allow modification of any of the PLA MMRs, except PLADIN. A PLA tool is provided in the development system to easily configure the PLA.

PROCESSOR REFERENCE PERIPHERALS

INTERRUPT SYSTEM

There are 25 interrupt sources on the ADuC7124 that are controlled by the interrupt controller. All interrupts are generated from the on-chip peripherals, except for the software interrupt (SWI) which is programmable by the user. The ARM7TDMI CPU core recognizes interrupts as one of two types: a normal interrupt request (IRQ) and a fast interrupt request (FIQ). All the interrupts can be masked separately.

The control and configuration of the interrupt system is managed through a number of interrupt-related registers. The bits in each IRQ and FIQ register represent the same interrupt source as described in Table 126.

The ADuC7124 contains a vectored interrupt controller (VIC) that supports nested interrupts up to eight levels. The VIC also allows the programmer to assign priority levels to all interrupt sources. Interrupt nesting must be enabled by setting the ENIRQN bit in the IRQCONN register. A number of extra MMRs are used when the full-vectored interrupt controller is enabled.

IRQSTA/FIQSTA should be saved immediately upon entering the interrupt service routine (ISR) to ensure that all valid interrupt sources are serviced.

Table 126. IRQ/FIQ MMRs Bit Designations

Bit	Description	Comments
0	All interrupts OR'ed (FIQ only)	This bit is set if any FIQ is active.
1	Software interrupt	User programmable interrupt source.
2	Timer0	General-Purpose Timer 0.
3	Timer1	General-Purpose Timer 1.
4	Timer2 or wake-up timer	General-Purpose Timer 2 or wake-up timer.
5	Timer3 or watchdog timer	General-Purpose Timer 3 or watchdog timer.
6	Flash Control 0	Flash controller for Block 0 interrupt.
7	Flash Control 1	Flash controller for Block 1 interrupt.
8	ADC	ADC interrupt source bit.
9	UART0	UART0 interrupt source bit.
10	UART1	UART1 interrupt source bit.
11	PLL lock	PLL lock bit.
12	I2C0 master IRQ	I ² C master interrupt source bit.
13	I2C0 slave IRQ	I ² C slave interrupt source bit.
14	I2C1 master IRQ	I ² C master interrupt source bit.
15	I2C1 slave IRQ	I ² C slave interrupt source bit.
16	SPI	SPI interrupt source bit.
17	XIRQ0 (GPIO IRQ0)	External Interrupt 0.
18	Comparator	Voltage comparator source bit.
19	PSM	Power supply monitor.
20	XIRQ1 (GPIO IRQ1)	External Interrupt 1.
21	PLA IRQ0	PLA Block 0 IRQ bit.

Bit	Description	Comments
22	XIRQ2 (GPIO IRQ2)	External Interrupt 2.
23	XIRQ3 (GPIO IRQ3)	External Interrupt 3.
24	PLA IRQ1	PLA Block 1 IRQ bit.
25	PWM	PWM trip interrupt source bit.

IRQ

The IRQ is the exception signal to enter the IRQ mode of the processor. It services general-purpose interrupt handling of internal and external events.

All 32 bits are logically OR'ed to create a single IRQ signal to the ARM7TDMI core. Descriptions of the four 32-bit registers dedicated to IRQ follow.

IRQSTA Register

IRQSTA is a read-only register that provides the current enabled IRQ source status (effectively a logic AND of the IRQSIG and IRQEN bits). When set to 1, that source generates an active IRQ request to the ARM7TDMI core. There is no priority encoder or interrupt vector generation. This function is implemented in software in a common interrupt handler routine.

IRQSTA Register

Name:	IRQSTA
Address:	0xFFFF0000
Default Value:	0x00000000
Access:	Read only

IRQSIG Register

IRQSIG reflects the status of the various IRQ sources. If a peripheral generates an IRQ signal, the corresponding bit in the IRQSIG is set; otherwise, it is cleared. The IRQSIG bits clear when the interrupt in the particular peripheral is cleared. All IRQ sources can be masked in the IRQEN MMR. IRQSIG is read only. This register should not be used in an interrupt service routine for determining the source of an IRQ exception; IRQSTA should only be used for this purpose.

IRQSIG Register

Name:	IRQSIG
Address:	0xFFFF0004
Default Value:	0x00000000
Access:	Read only

IRQEN Register

IRQEN provides the value of the current enable mask. When a bit is set to 1, the corresponding source request is enabled to create an IRQ exception. When a bit is set to 0, the corresponding source request is disabled or masked, which does not create an IRQ exception. The IRQEN register cannot be used to disable an interrupt.

IRQEN Register

Name: IRQEN
Address: 0xFFFF0008
Default Value: 0x00000000
Access: Read/write

IRQCLR Register

IRQCLR is a write-only register that allows the IRQEN register to clear to mask an interrupt source. Each bit that is set to 1 clears the corresponding bit in the IRQEN register without affecting the remaining bits. The pair of registers, IRQEN and IRQCLR, allow independent manipulation of the enable mask without requiring an atomic read-modify-write.

This register should be used to disable an interrupt source only when:

- In the interrupt sources interrupt service routine.
- The peripheral is temporarily disabled by its own control register.

This register should not be used to disable an IRQ source if that IRQ source has an interrupt pending or could have an interrupt pending.

IRQCLR Register

Name: IRQCLR
Address: 0xFFFF000C
Default Value: 0x00000000
Access: Write only

FAST INTERRUPT REQUEST (FIQ)

The fast interrupt request (FIQ) is the exception signal to enter the FIQ mode of the processor. It is provided to service data transfer or communication channel tasks with low latency. The FIQ interface is identical to the IRQ interface and provides the second level interrupt (highest priority). Four 32-bit registers are dedicated to FIQ: FIQSIG, FIQEN, FIQCLR, and FIQSTA.

Bit 31 to Bit 1 of FIQSTA are logically OR'ed to create the FIQ signal to the core and to Bit 0 of both the FIQ and IRQ registers (FIQ source).

The logic for FIQEN and FIQCLR does not allow an interrupt source to be enabled in both IRQ and FIQ masks. A bit set to 1 in FIQEN clears, as a side effect, the same bit in IRQEN. Likewise, a

bit set to 1 in IRQEN clears, as a side effect, the same bit in FIQEN. An interrupt source can be disabled in both the IRQEN and FIQEN masks.

FIQSIG

FIQSIG reflects the status of the different FIQ sources. If a peripheral generates an FIQ signal, the corresponding bit in the FIQSIG is set; otherwise, it is cleared. The FIQSIG bits are cleared when the interrupt in the particular peripheral is cleared. All FIQ sources can be masked in the FIQEN MMR. FIQSIG is read only.

FIQSIG Register

Name: FIQSIG
Address: 0xFFFF0104
Default Value: 0x00000000
Access: Read only

FIQEN

FIQEN provides the value of the current enable mask. When a bit is set to 1, the corresponding source request is enabled to create an FIQ exception. When a bit is set to 0, the corresponding source request is disabled or masked which does not create an FIQ exception. The FIQEN register cannot be used to disable an interrupt.

FIQEN Register

Name: FIQEN
Address: 0xFFFF0108
Default Value: 0x00000000
Access: Read/write

FIQCLR

FIQCLR is a write-only register that allows the FIQEN register to clear to mask an interrupt source. Each bit that is set to 1 clears the corresponding bit in the FIQEN register without affecting the remaining bits. The pair of registers, FIQEN and FIQCLR, allows independent manipulation of the enable mask without requiring an atomic read-modify-write.

This register should be used to disable an interrupt source only when:

- In the interrupt sources interrupt service routine.
- The peripheral is temporarily disabled by its own control register.

This register should not be used to disable an IRQ source if that IRQ source has an interrupt pending or could have an interrupt pending.

FIQCLR Register

Name: FIQCLR
 Address: 0xFFFFF010C
 Default Value: 0x00000000
 Access: Write only

FIQSTA

FIQSTA is a read-only register that provides the current enabled FIQ source status (effectively a logic AND of the FIQSIG and FIQEN bits). When set to 1, that source generates an active FIQ request to the ARM7TDMI core. There is no priority encoder or interrupt vector generation. This function is implemented in software in a common interrupt handler routine.

FIQSTA Register

Name: FIQSTA
 Address: 0xFFFFF0100
 Default Value: 0x00000000
 Access: Read only

Programmed Interrupts

Because the programmed interrupts are not maskable, they are controlled by another register (SWICFG) that writes into the IRQSTA and IRQSIG registers and/or the FIQSTA and FIQSIG registers at the same time.

The 32-bit register dedicated to software interrupt is SWICFG (described in Table 127). This MMR allows control of a programmed source interrupt.

Table 127. SWICFG MMR Bit Designations

Bit	Description
31:3	Reserved.
2	Programmed interrupt FIQ. Setting/clearing this bit corresponds to setting/clearing Bit 1 of FIQSTA and FIQSIG.
1	Programmed interrupt IRQ. Setting/clearing this bit corresponds to setting/clearing Bit 1 of IRQSTA and IRQSIG.
0	Reserved.

Any interrupt signal must be active for at least the minimum interrupt latency time to be detected by the interrupt controller and to be detected by the user in the IRQSTA/FIQSTA register.

Figure 51. Interrupt Structure

VECTORED INTERRUPT CONTROLLER (VIC)

The ADUC7124 incorporates an enhanced interrupt control system or (vectored interrupt controller). The vectored interrupt controller for IRQ interrupt sources is enabled by setting Bit 0 of the IRQCONN register. Similarly, Bit 1 of IRQCONN enables the vectored interrupt controller for the FIQ interrupt sources. The vectored interrupt controller provides the following enhancements to the standard IRQ/FIQ interrupts:

- Vectored interrupts—allows a user to define separate interrupt service routine addresses for every interrupt source. This is achieved by using the IRQBASE and IRQVEC registers.
- IRQ/FIQ interrupts—can be nested up to eight levels depending on the priority settings. An FIQ still has a higher priority than an IRQ. Therefore, if the VIC is enabled for both the FIQ and IRQ and prioritization is maximized, it is possible to have 16 separate interrupt levels.
- Programmable interrupt priorities—using the IRQP0 to IRQP3 registers, an interrupt source can be assigned an interrupt priority level value between 0 and 7.

VIC MMRs

IRQBASE Register

The vector base register, IRQBASE, is used to point to the start address of memory used to store 32 pointer addresses. These pointer addresses are the addresses of the individual interrupt service routines.

Name: IRQBASE
 Address: 0xFFFFF0014
 Default Value: 0x00000000
 Access: Read/write

Table 128. IRQBASE MMR Bit Designations

Bit	Type	Initial Value	Description
31:16	Read only	Reserved	Always read as 0.
15:0	R/W	0	Vector base address.

ADuC7124

IRQVEC Register

The IRQ interrupt vector register, IRQVEC points to a memory address containing a pointer to the interrupt service routine of the currently active IRQ. This register should only be read when an IRQ occurs and IRQ interrupt nesting has been enabled by setting Bit 0 of the IRQCONN register.

Name: IRQVEC
 Address: 0xFFFF001C
 Default Value: 0x00000000
 Access: Read only

Table 129. IRQVEC MMR Bit Designations

Bit	Type	Initial Value	Description
31:23	Read only	0	Always read as 0.
22:7	R/W	0	IRQBASE register value.
6:2	Read only	0	Highest priority source. This is a value between 0 and 27 representing the possible interrupt sources. For example, if the highest currently active IRQ is Timer 2, then these bits are [00100].
1:0	Reserved	0	Reserved bits.

Priority Registers

The IRQ interrupt vector register, IRQVEC points to a memory address containing a pointer to the interrupt service routine of the currently active IRQ. This register should only be read when an IRQ occurs and IRQ interrupt nesting has been enabled by setting Bit 0 of the IRQCONN register.

IRQP0 Register

Name: IRQP0
 Address: 0xFFFF0020
 Default Value: 0x00000000
 Access: Read/write

Table 130. IRQP0 MMR Bit Designations

Bit	Name	Description
31	Reserved	Reserved bit.
30:28	Flash1PI	A priority level of 0 to 7 can be set for the Flash Block 1 controller interrupt source.
27	Reserved	Reserved bit.
26:24	Flash0PI	A priority level of 0 to 7 can be set for the Flash Block 0 controller interrupt source.
23	Reserved	Reserved bit.
22:20	T3PI	A priority level of 0 to 7 can be set for Timer 3.
19	Reserved	Reserved bit.

Bit	Name	Description
18:16	T2PI	A priority level of 0 to 7 can be set for Timer2.
15	Reserved	Reserved bit.
14:12	T1PI	A priority level of 0 to 7 can be set for Timer1.
11	Reserved	Reserved bit.
10:8	T0PI	A priority level of 0 to 7 can be set for Timer0.
7	Reserved	Reserved bit.
6:4	SWINTP	A priority level of 0 to 7 can be set for the software interrupt source.
3:0	Reserved	Interrupt 0 cannot be prioritized.

IRQP1 Register

Name: IRQP1
 Address: 0xFFFF0024
 Default Value: 0x00000000
 Access: Read/write

Table 131. IRQP1 MMR Bit Designations

Bit	Name	Description
31	Reserved	Reserved bit.
30:28	I2C1SPI	A priority level of 0 to 7 can be set for the I2C1 slave.
27	Reserved	Reserved bit.
26:24	I2C1MPI	A priority level of 0 to 7 can be set for the I2C1 master.
23	Reserved	Reserved bit.
22:20	I2C0SPI	A priority level of 0 to 7 can be set for the I2C0 slave.
19	Reserved	Reserved bit.
18:16	I2C0MPI	A priority level of 0 to 7 can be set for the I ² C 0 master.
15	Reserved	Reserved bit.
14:12	PLLPI	A priority level of 0 to 7 can be set for the PLL lock interrupt.
11	Reserved	Reserved bit.
10:8	UART1PI	A priority level of 0 to 7 can be set for UART1.
7	Reserved	Reserved bit.
6:4	UART0PI	A priority level of 0 to 7 can be set for UART0.
5	Reserved	Reserved bit.
2:0	ADCP1	A priority level of 0 to 7 can be set for the ADC interrupt source.

IRQP2 Register

Name: IRQP2
 Address: 0xFFFF0028
 Default Value: 0x00000000
 Access: Read/write

Table 132. IRQP2 MMR Bit Designations

Bit	Name	Description
31	Reserved	Reserved bit.
30:28	IRQ3PI	A priority level of 0 to 7 can be set for IRQ3.
27	Reserved	Reserved bit.
26:24	IRQ2PI	A priority level of 0 to 7 can be set for IRQ2.
23	Reserved	Reserved bit.
22:20	PLA0PI	A priority level of 0 to 7 can be set for PLA IRQ0.
19	Reserved	Reserved bit.
18:16	IRQ1PI	A priority level of 0 to 7 can be set for IRQ1.
15	Reserved	Reserved bit.
14:12	PSMPI	A priority level of 0 to 7 can be set for the power supply monitor interrupt source.
11	Reserved	Reserved bit.
10:8	COMPI	A priority level of 0 to 7 can be set for the comparator.
7	Reserved	Reserved bit.
6:4	IRQ0PI	A priority level of 0 to 7 can be set for IRQ0.
3	Reserved	Reserved bit.
2:0	SPIPI	A priority level of 0 to 7 can be set for SPI.

IRQP3 Register

Name: IRQP3
 Address: 0xFFFF002C
 Default Value: 0x00000000
 Access: Read/write

Table 133. IRQP3 MMR Bit Designations

Bit	Name	Description
31:7	Reserved	Reserved bit.
6:4	PWMPI	A priority level of 0 to 7 can be set for PWM.
3	Reserved	Reserved bit.
2:0	PLA1PI	A priority level of 0 to 7 can be set for PLA IRQ1.

IRQCONN Register

The IRQCONN register is the IRQ and FIQ control register. It contains two active bits: the first to enable nesting and prioritization of IRQ interrupts and the other to enable nesting and prioritization of FIQ interrupts.

If these bits are cleared, FIQs and IRQs can still be used, but it is not possible to nest IRQs or FIQs, nor is it possible to set an

interrupt source priority level. In this default state, an FIQ does have a higher priority than an IRQ.

Name: IRQCONN
 Address: 0xFFFF0030
 Default Value: 0x00000000
 Access: Read/write

Table 134. IRQCONN MMR Bit Designations

Bit	Name	Description
31:2	Reserved	These bits are reserved and should not be written to.
1	ENFIQN	Setting this bit to 1 enables nesting of FIQ interrupts. Clearing this bit means no nesting or prioritization of FIQs is allowed.
0	ENIRQN	Setting this bit to 1 enables nesting of IRQ interrupts. Clearing this bit means no nesting or prioritization of IRQs is allowed.

IRQSTAN Register

If IRQCONN.0 is asserted and IRQVEC is read, one of these bits is asserted. The bit that asserts depends on the priority of the IRQ. If the IRQ is of Priority 0, then Bit 0 asserts, if Priority 1, then Bit 1 asserts, and so on. When a bit is set in this register, all interrupts of that priority and lower are blocked.

To clear a bit in this register, all bits of a higher priority must be cleared first. It is only possible to clear one bit at a time. For example, if this register is set to 0x09, writing 0xFF changes the register to 0x08, and writing 0xFF a second time changes the register to 0x00.

Name: IRQSTAN
 Address: 0xFFFF003C
 Default Value: 0x00000000
 Access: Read/write

Table 135. IRQSTAN MMR Bit Designations

Bit	Name	Description
31:8	Reserved	These bits are reserved and should not be written to.
7:0		Setting this bit to 1 enables nesting of FIQ interrupts. Clearing this bit, means no nesting or prioritization of FIQs is allowed.

ADuC7124

FIQVEC Register

The FIQ interrupt vector register, FIQVEC, points to a memory address containing a pointer to the interrupt service routine of the currently active FIQ. This register should be read only when an FIQ occurs and FIQ interrupt nesting has been enabled by setting Bit 1 of the IRQCONN register.

Name: FIQVEC
 Address: 0xFFFF011C
 Default Value: 0x00000000
 Access: Read only

Table 136. FIQVEC MMR Bit Designations

Bit	Type	Initial Value	Description
31:23	Read only	0	Always read as 0.
22:7	R/W	0	IRQBASE register value.
6:2		0	Highest priority source. This is a value between 0 and 27, representing the currently active interrupt source. The interrupts are listed in Table 126. For example, if the highest currently active FIQ is Timer2, then these bits are [00100].
1:0	Reserved	0	Reserved bits.

FIQSTAN Register

If IRQCONN.1 is asserted and FIQVEC is read, one of these bits assert. The bit that asserts depends on the priority of the FIQ. If the FIQ is of Priority 0, Bit 0 asserts, if Priority 1, Bit 1 asserts, and so forth.

When a bit is set in this register all interrupts of that priority and lower are blocked.

To clear a bit in this register, all bits of a higher priority must be cleared first. It is possible to clear only one bit at a time. For example, if this register is set to 0x09, then writing 0xFF changes

Table 138. IRQCONE MMR Bit Designations

Bit	Value	Name	Description
31:12		Reserved	These bits are reserved and should not be written to.
11:10	11 10 01 00	PLA1SRC[1:0]	PLA IRQ1 triggers on falling edge. PLA IRQ1 triggers on rising edge. PLA IRQ1 triggers on low level. PLA IRQ1 triggers on high level.
9:8	11 10 01 00	IRQ3SRC[1:0]	External IRQ3 triggers on falling edge. External IRQ3 triggers on rising edge. External IRQ3 triggers on low level. External IRQ3 triggers on high level.

the register to 0x08 and writing 0xFF a second time changes the register to 0x00.

Name: FIQSTAN
 Address: 0xFFFF013C
 Default Value: 0x00000000
 Access: Read/write

Table 137. FIQSTAN MMR Bit Designations

Bit	Name	Description
31:8	Reserved	These bits are reserved and should not be written to.
7:0		Setting this bit to 1 enables nesting of FIQ interrupts. Clearing this bit, means no nesting or prioritization of FIQs is allowed.

External Interrupts and PLA interrupts

The ADuC7124 provides up to four external interrupt sources and two PLA interrupt sources. These external interrupts can be individually configured as level or rising/falling edge triggered.

To enable the external interrupt source or the PLA interrupt source, first, the appropriate bit must be set in the FIQEN or IRQEN register. To select the required edge or level to trigger on, the IRQCONE register must be appropriately configured.

To properly clear an edge-based external IRQ interrupt or an edge-based PLA interrupt, set the appropriate bit in the IRQCLRE register.

IRQCONE Register

Name: IRQCONE
 Address: 0xFFFF0034
 Default Value: 0x00000000
 Access: Read/write

Bit	Value	Name	Description
7:6	11	IRQ2SRC[1:0]	External IRQ2 triggers on falling edge.
	10		External IRQ2 triggers on rising edge.
	01		External IRQ2 triggers on low level.
	00		External IRQ2 triggers on high level.
5:4	11	PLA0SRC[1:0]	PLA IRQ0 triggers on falling edge.
	10		PLA IRQ0 triggers on rising edge.
	01		PLA IRQ0 triggers on low level.
	00		PLA IRQ0 triggers on high level.
3:2	11	IRQ1SRC[1:0]	External IRQ1 triggers on falling edge.
	10		External IRQ1 triggers on rising edge.
	01		External IRQ1 triggers on low level.
	00		External IRQ1 triggers on high level.
1:0	11	IRQ0SRC[1:0]	External IRQ0 triggers on falling edge.
	10		External IRQ0 triggers on rising edge.
	01		External IRQ0 triggers on low level.
	00		External IRQ0 triggers on high level.

IRQCLRE Register

Name:	IRQCLRE
Address:	0xFFFF0038
Default Value:	0x00000000
Access:	Read/write

Table 139. IRQCLRE MMR Bit Designations

Bit	Name	Description
31:25	Reserved	These bits are reserved and should not be written to.
24	PLA1CLRI	A 1 must be written to this bit in the PLA IRQ1 interrupt service routine to clear an edge-triggered PLA IRQ1 interrupt.
23	IRQ3CLRI	A 1 must be written to this bit in the external IRQ3 interrupt service routine to clear an edge-triggered IRQ3 interrupt.
22	IRQ2CLRI	A 1 must be written to this bit in the external IRQ2 interrupt service routine to clear an edge-triggered IRQ2 interrupt.
21	PLA0CLRI	A 1 must be written to this bit in the PLA IRQ0 interrupt service routine to clear an edge-triggered PLA IRQ0 interrupt.
20	IRQ1CLRI	A 1 must be written to this bit in the external IRQ1 interrupt service routine to clear an edge-triggered IRQ1 interrupt.
19:18	Reserved	These bits are reserved and should not be written to.
17	IRQ0CLRI	A 1 must be written to this bit in the external IRQ0 interrupt service routine to clear an edge-triggered IRQ0 interrupt.
16:0	Reserved	These bits are reserved and should not be written to.

TIMERS

The ADuC7124 has four general-purpose timer/counters.

- Timer0
- Timer1
- Timer2 or wake-up timer
- Timer3 or watchdog timer

These four timers in their normal mode of operation can be either free running or periodic.

In free-running mode, the counter decreases from the maximum value until zero scale is reached and starts again at the minimum value. It also increases from the minimum value until full scale is reached and starts again at the maximum value.

In periodic mode, the counter decrements/increments from the value in the load register (TxLD MMR) until zero/full scale is reached and starts again at the value stored in the load register.

The timer interval is calculated as follows:

$$Interval = \frac{(TxD) \times Prescaler}{Source\ Clock}$$

The value of a counter can be read at any time by accessing its value register (TxVAL). Note that, when a timer is being clocked from a clock other than a core clock, an incorrect value may be read (due to asynchronous clock system). In this configuration, TxVAL should always be read twice. If the two readings are different, it should be read a third time to get the correct value.

Timers are started by writing in the control register of the corresponding timer (TxCON).

In normal mode, an IRQ is generated each time the value of the counter reaches zero when counting down. It is also generated each time the counter value reaches full scale when counting up. An IRQ can be cleared by writing any value to clear the register of that particular timer (TxCLRI).

When using an asynchronous clock-to-clock timer, the interrupt in the timer block can take more time to clear than the time it takes for the code in the interrupt routine to execute. Ensure that the interrupt signal is cleared before leaving the interrupt service routine. This can be done by checking the IRQSTA MMR.

Timer0 (RTOS Timer)

Timer0 is a general-purpose, 16-bit timer (count down) with a programmable prescaler. The prescaler source is the core clock frequency (HCLK) and can be scaled by factors of 1, 16, or 256.

Timer0 can be used to start ADC conversions as shown in the block diagram in Figure 52.

Figure 52. Timer0 Block Diagram

The Timer0 interface consists of four MMRs: TOLD, TOVAL, TOCON, and T0CLRI.

TOLD Register

Name:	TOLD
Address:	0xFFFF0300
Default Value:	0x0000
Access:	Read/write

TOLD is a 16-bit load register.

TOVAL Register

Name:	TOVAL
Address:	0xFFFF0304
Default Value:	0xFFFF
Access:	Read

TOVAL is a 16-bit read-only register representing the current state of the counter.

TOCON Register

Name:	TOCON
Address:	0xFFFF0308
Default Value:	0x0000
Access:	Read/write

TOCON is the configuration MMR described in Table 140.

Table 140. T0CON MMR Bit Descriptions

Bit	Value	Description
31:8		Reserved.
7		Timer0 enable bit. Set by the user to enable Timer0. Cleared by the user to disable Timer0 by default.
6		Timer0 mode. Set by the user to operate in periodic mode. Cleared by the user to operate in free-running mode. Default mode.
5:4		Clock select bits.
	00	HCLK.
	01	UCLK.
	10	32.768 kHz.
3:2	11	Reserved.
		Prescale.
	00	Core clock/1. Default value.
	01	Core clock/16.
10		Core clock/256.
	11	Undefined. Equivalent to 00.
1:0		Reserved.

T0CLR Register

Name: T0CLR
 Address: 0xFFFF030C
 Default Value: 0xFF
 Access: Write only

T0CLR is an 8-bit register. Writing any value to this register clears the interrupt.

Timer1 (General-Purpose Timer)

Timer1 is a general-purpose, 32-bit timer (count down or count up) with a programmable prescaler. The source can be the 32 kHz external crystal, the undivided system, the core clock, or P1.1 (maximum frequency 41.78 MHz). This source can be scaled by a factor of 1, 16, 256, or 32,768.

The counter can be formatted as a standard 32-bit value or as hours: minutes: seconds: hundredths.

Timer1 has a capture register (T1CAP) that can be triggered by a selected IRQ source initial assertion. This feature can be used to determine the assertion of an event more accurately than the precision allowed by the RTOS timer when the IRQ is serviced.

Timer1 can be used to start ADC conversions.

Figure 53. Timer1 Block Diagram

The Timer1 interface consists of five MMRs: T1LD, T1VAL, T1CON, T1CLR, and T1CAP.

T1LD Register

Name: T1LD
 Address: 0xFFFF0320
 Default Value: 0x00000000
 Access: Read/write

T1LD is a 32-bit load register.

T1VAL Register

Name: T1VAL
 Address: 0xFFFF0324
 Default Value: 0xFFFFFFFF
 Access: Read only

T1VAL is a 32-bit read-only register that represents the current state of the counter.

T1CON Register

Name: T1CON
 Address: 0xFFFF0328
 Default Value: 0x0000
 Access: Read/write

T1CON is the configuration MMR described in Table 141.

Table 141. T1CON MMR Bit Descriptions

Bit	Value	Description
31:18		Reserved.
17		Event select bit. Set by the user to enable time capture of an event. Cleared by the user to disable time capture of an event.
16:12		Event select range, 0 to 31. These events are as described in Table 126. All events are offset by two, that is, Event 2 in Table 126 becomes Event 0 for the purposes of Timer1.
11:9		Clock select.
	000	Core clock (41 MHz/2 ^{CD}).
	001	32.768 kHz.
	010	UCLK.
	011	P1.0 raising edge triggered.
8		Count up. Set by the user for Timer1 to count up. Cleared by the user for Timer1 to count down by default.
7		Timer1 enable bit. Set by the user to enable Timer1. Cleared by the user to disable Timer1 by default.
6		Timer1 mode. Set by the user to operate in periodic mode. Cleared by the user to operate in free-running mode. Default mode.
5:4		Format.
	00	Binary.
	01	Reserved.
	10	Hr: min: sec: hundredths (23 hours to 0 hour).
	11	Hr: min: sec: hundredths (255 hours to 0 hour).
3:0		Prescale.
	0000	Source clock/1.
	0100	Source clock/16.
	1000	Source clock/256.
	1111	Source clock/32,768.

T1CLRI Register

Name: T1CLRI
Address: 0xFFFF032C
Default Value: 0xFF
Access: Read/write

T1CLRI is an 8-bit register. Writing any value to this register clears the Timer1 interrupt.

T1CAP Register

Name: T1CAP
Address: 0xFFFF0330
Default Value: 0x00000000
Access: Read only

T1CAP is a 32-bit register. It holds the value contained in T1VAL when a particular event occurs. This event must be selected in T1CON.

Timer2 (Wake-Up Timer)

Timer2 is a 32-bit wake-up timer, count down or count up, with a programmable prescaler. The prescaler is clocked directly from one of four clock sources, including the core clock (default selection), the internal 32.768 kHz oscillator, the external 32.768 kHz watch crystal, or the PLL undivided clock. The selected clock source can be scaled by a factor of 1, 16, 256, or 32,768. The wake-up timer continues to run when the core clock is disabled. This gives a minimum resolution of 22 ns when the core is operating at 41.78 MHz and with a prescaler of 1. Capture of the current timer value is enabled if the Timer2 interrupt is enabled via IRQEN[4] (see Table 126).

The counter can be formatted as a plain 32-bit value or as hours: minutes: seconds: hundredths.

Timer2 reloads the value from T2LD either when Timer2 overflows or immediately when T2ICLR is written.

The Timer2 interface consists of four MMRs, shown in Table 142.

Table 142. Timer2 Interface Registers

Register	Description
T2LD	32-bit register. Holds 32-bit unsigned integers.
T2VAL	32-bit register. Holds 32-bit unsigned integers. This register is read only.
T2CLRI	8-bit register. Writing any value to this register clears the Timer2 interrupt.
T2CON	Configuration MMR.

Timer2 Load Registers

Name: T2LD
Address: 0xFFFF0340
Default Value: 0x00000
Access: Read/write

T2LD is a 32-bit register, which holds the 32-bit value that is loaded into the counter.

Timer2 Clear Register

Name: T2CLRI
Address: 0xFFFF034C
Default Value: 0x00
Access: Write only

This 8-bit write-only MMR is written (with any value) by user code to refresh (reload) Timer2.

Timer2 Value Register

Name: T2VAL
 Address: 0xFFFF0344
 Default Value: 0x0000
 Access: Read only

T2VAL is a 32-bit register that holds the current value of Timer2.

Timer2 Control Register

Name: T2CON
 Address: 0xFFFF0348
 Default Value: 0x0000
 Access: Read/write

This 32-bit MMR configures the mode of operation for Timer2.

Table 143. T2CON MMR Bit Designations

Bit	Value	Description
31:11		Reserved.
10:9		Clock source select.
	00	External 32.768 kHz watch crystal (default).
	01	External 32.768 kHz watch crystal.
	10	Internal 32.768 kHz oscillator.
	11	HCLK.
8		Count up. Set by the user for Timer2 to count up. Cleared by the user for Timer2 to count down (default).
7		Timer2 enable bit. Set by the user to enable Timer2. Cleared by the user to disable Timer2 (default).
6		Timer2 mode. Set by the user to operate in periodic mode. Cleared by the user to operate in free-running mode (default).
5:4		Format.
	00	Binary (default).
	01	Reserved.
	10	Hr: min: sec: hundredths (23 hours to 0 hours).
	11	Hr: min: sec: hundredths (255 hours to 0 hours).
3:0		Prescaler.
	0000	Source clock/1 (default).
	0100	Source clock/16.
	1000	Source clock/256. This setting should be used in conjunction with Timer2 Format 10 and Format 11.
	1111	Source clock/32,768.

Timer3 (Watchdog Time)

Timer3 has two modes of operation: normal mode and watchdog mode. The watchdog timer is used to recover from an illegal software state. Once enabled, it requires periodic servicing to prevent it from forcing a processor reset.

Normal Mode

Timer3 in normal mode is identical to Timer0, except for the clock source and the count-up functionality. The clock source is 32 kHz from the PLL and can be scaled by a factor of 1, 16, or 256 (see Figure 54).

Figure 54. Timer3 Block Diagram

Watchdog Mode

Watchdog mode is entered by setting Bit 5 in the T3CON MMR. Timer3 decreases from the value present in the T3LD register until 0 is reached. T3LD is used as the timeout. The maximum timeout can be 512 sec using the prescaler/256 and full-scale in T3LD. Timer3 is clocked by the internal 32 kHz crystal when operating in the watchdog mode. Note that, to enter watchdog mode successfully, Bit 5 in the T3CON MMR must be set after writing to the T3LD MMR.

If the timer reaches 0, a reset or an interrupt occurs, depending on Bit 1 in the T3CON register. To avoid reset or interrupt, any value must be written to T3CLR1 before the expiration period. This reloads the counter with T3LD and begins a new timeout period.

When watchdog mode is entered, T3LD and T3CON are write-protected. These two registers cannot be modified until a reset clears the watchdog enable bit, which causes Timer3 to exit watchdog mode.

The Timer3 interface consists of four MMRs: T3LD, T3VAL, T3CON, and T3CLR1.

T3LD Register

Name: T3LD
 Address: 0xFFFF0360
 Default Value: 0x0000
 Access: Read/write

T3LD is a 16-bit load register.

T3VAL Register

Name: T3VAL
 Address: 0xFFFF0364
 Default Value: 0xFFFF
 Access: Read only

T3VAL is a 16-bit read-only register that represents the current state of the counter.

T3CON Register

Name: T3CON
 Address: 0xFFFF0368
 Default Value: 0x0000
 Access: Read/write

T3CON is the configuration MMR described in Table 144.

Table 144. T3CON MMR Bit Descriptions

Bit	Value	Description
31:9		Reserved.
8		Count up. Set by the user for Timer3 to count up. Cleared by the user for Timer3 to count down by default.
7		Timer3 enable bit. Set by the user to enable Timer3. Cleared by the user to disable Timer3 by default.
6		Timer3 mode. Set by the user to operate in periodic mode. Cleared by the user to operate in free-running mode (default mode).
5		Watchdog mode enable bit. Set by the user to enable watchdog mode. Cleared by the user to disable watchdog mode by default.
4		Secure clear bit. Set by the user to use the secure clear option. Cleared by the user to disable the secure clear option by default.
3:2		Prescale.
	00	Source clock/1 by default.
	01	Source clock/16.
	10	Source clock/256.
	11	Undefined. Equivalent to 00.
1		Watchdog IRQ option bit. Set by the user to produce an IRQ instead of a reset when the watchdog reaches 0. Cleared by the user to disable the IRQ option.
0		Reserved.

T3CLRI Register

Name:	T3CLRI
Address:	0xFFFF036C
Default Value:	0x00
Access:	Write only

T3CLRI is an 8-bit register. Writing any value to this register on successive occasions clears the Timer3 interrupt in normal mode or resets a new timeout period in watchdog mode.

Note that the user must perform successive writes to this register to ensure resetting the timeout period.

Secure Clear Bit (Watchdog Mode Only)

The secure clear bit is provided for a higher level of protection. When set, a specific sequential value must be written to T3CLRI to avoid a watchdog reset. The value is a sequence generated by the 8-bit linear feedback shift register (LFSR) polynomial = $X^8 + X^6 + X^5 + X + 1$, as shown in Figure 55.

Figure 55. 8-Bit LFSR

The initial value or seed is written to T3CLRI before entering watchdog mode. After entering watchdog mode, a write to T3CLRI must match this expected value. If it matches, the LFSR is advanced to the next state when the counter reload occurs. If it fails to match the expected state, a reset is immediately generated, even if the count has not yet expired.

The value 0x00 should not be used as an initial seed due to the properties of the polynomial. The value 0x00 is always guaranteed to force an immediate reset. The value of the LFSR cannot be read; it must be tracked/generated in software.

Example of a sequence:

1. Enter initial seed, 0xAA, in T3CLRI before starting Timer3 in watchdog mode.
2. Enter 0xAA in T3CLRI; Timer3 is reloaded.
3. Enter 0x37 in T3CLRI; Timer3 is reloaded.
4. Enter 0x6E in T3CLRI; Timer3 is reloaded.
5. Enter 0x66. 0xDC was expected; the watchdog resets the chip.

HARDWARE DESIGN CONSIDERATIONS

POWER SUPPLIES

The ADuC7124 operational power supply voltage range is 2.7 V to 3.6 V. Separate analog and digital power supply pins (AV_{DD} and IOV_{DD} , respectively) allow AV_{DD} to be kept relatively free of noisy digital signals often present on the system IOV_{DD} line. In this mode, the part can also operate with split supplies; that is, it can use different voltage levels for each supply. For example, the system can be designed to operate with an IOV_{DD} voltage level of 3.3 V while the AV_{DD} level can be at 3 V or vice versa. A typical split supply configuration is shown in Figure 56.

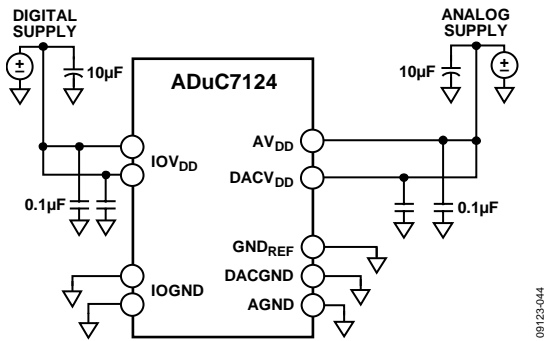

Figure 56. External Dual Supply Connections

As an alternative to providing two separate power supplies, the user can reduce noise on AV_{DD} by placing a small series resistor and/or ferrite bead between AV_{DD} and IOV_{DD} and then decoupling AV_{DD} separately to ground. An example of this configuration is shown in Figure 57. With this configuration, other analog circuitry (such as op amps, voltage reference, or any other analog circuitry) can be powered from the AV_{DD} supply line as well.

Figure 57. External Single Supply Connections

Notice that in both Figure 56 and Figure 57, a large value (10 μF) reservoir capacitor sits on IOV_{DD} , and a separate 10 μF capacitor sits on AV_{DD} . In addition, local small-value (0.1 μF) capacitors are located at each AV_{DD} and IOV_{DD} pin of the chip. As per standard design practice, be sure to include all of these capacitors and ensure that the smaller capacitors are close to each AV_{DD} pin with trace lengths as short as possible. Connect the ground terminal of each of these capacitors directly to the underlying ground plane.

Finally, note that the analog and digital ground pins on the ADuC7124 must be referenced to the same system ground reference point at all times.

IOV_{DD} Supply Sensitivity

The IOV_{DD} supply is sensitive to high frequency noise because it is the supply source for the internal oscillator and PLL circuits. When the internal PLL loses lock, the clock source is removed by a gating circuit from the CPU, and the ARM7TDMI core stops executing code until the PLL regains lock. This feature ensures that no flash interface timings or ARM7TDMI timings are violated.

Typically, frequency noise greater than 50 kHz and 50 mV p-p on top of the supply causes the core to stop working.

If decoupling values recommended in the Power Supplies section do not sufficiently dampen all noise sources below 50 mV on IOV_{DD} , a filter such as the one shown in Figure 58 is recommended.

Figure 58. Recommended IOV_{DD} Supply Filter

Linear Voltage Regulator

The ADuC7124 requires a single 3.3 V supply, but the core logic requires a 2.6 V supply. An on-chip linear regulator generates the 2.6 V from IOV_{DD} for the core logic. The LV_{DD} pin is the 2.6 V supply for the core logic. An external compensation capacitor of 0.47 μF must be connected between LV_{DD} and $DGND$ (as close as possible to these pins) to act as a tank of charge as shown in Figure 59.

Figure 59. Voltage Regulator Connections

The LV_{DD} pin should not be used for any other chip. It is also recommended to use excellent power supply decoupling on IOV_{DD} to help improve line regulation performance of the on-chip voltage regulator.

GROUNDING AND BOARD LAYOUT RECOMMENDATIONS

As with all high resolution data converters, special attention must be paid to grounding and PC board layout of the ADuC7124-based designs to achieve optimum performance from the ADCs and DAC.

Although the part has separate pins for analog and digital ground (AGND and IOGND), the user must not tie these to two separate ground planes unless the two ground planes are connected very close to the part. This is illustrated in the simplified example shown in Figure 60a. In systems where digital and analog ground planes are connected together somewhere else (at the power supply of the system, for example), the planes cannot be reconnected near the part because a ground loop results. In these cases, tie all the ADuC7124 AGND and IOGND pins to the analog ground plane, as illustrated in Figure 60b. In systems with only one ground plane, ensure that the digital and analog components are physically separated onto separate halves of the board so that digital return currents do not flow near analog circuitry (and vice versa).

The ADuC7124 can then be placed between the digital and analog sections, as illustrated in Figure 60c.

Figure 60. System Grounding Schemes

In all of these scenarios, and in more complicated real-life applications, the users should pay particular attention to the flow of current from the supplies and back to ground. Make sure the return paths for all currents are as close as possible to the paths the currents took to reach their destinations.

For example, do not power components on the analog side (as seen in Figure 60b) with IOV_{DD} because that forces return currents from IOV_{DD} to flow through AGND. Avoid digital currents flowing under analog circuitry, which can occur if a noisy digital chip is placed on the left half of the board (shown in Figure 60c). If possible, avoid large discontinuities in the ground plane(s), such as those formed by a long trace on the same layer, because they force return signals to travel a longer path. In addition, make all connections to the ground plane directly, with little or no trace separating the pin from its via to ground.

When connecting fast logic signals (rise/fall time < 5 ns) to any of the ADuC7124 digital inputs, add a series resistor to each relevant line to keep rise and fall times longer than 5 ns at the input pins of the part. A value of 100 Ω or 200 Ω is usually sufficient to prevent high speed signals from coupling capacitively into the part and affecting the accuracy of ADC conversions.

CLOCK OSCILLATOR

The clock source for the ADuC7124 can be generated by the internal PLL or by an external clock input. To use the internal PLL, connect a 32.768 kHz parallel resonant crystal between XCLKI and XCLKO, and connect a capacitor from each pin to ground as shown in Figure 61. The crystal allows the PLL to lock correctly to give a frequency of 41.78 MHz. If no external crystal is present, the internal oscillator is used to give a typical frequency of 32.768 kHz \pm 3%.

Figure 61. External Parallel Resonant Crystal Connections

To use an external source clock input instead of the PLL (see Figure 62), Bit 1 and Bit 0 of PLLCON must be modified. The external clock uses P0.7 and XCLK.

Figure 62. Connecting an External Clock Source

Using an external clock source, the ADuC7124 specified operational clock speed range is 50 kHz to 41.78 MHz \pm 1%, which ensures correct operation of the analog peripherals and Flash/EE.

ADuC7124

POWER-ON RESET OPERATION

An internal power-on reset (POR) is implemented on the ADuC7124. For V_{DD} below 2.40 V typical, the internal POR holds the part in reset. As V_{DD} rises above 2.40 V, an internal timer times out for typically 128 ms before the part is released from reset. The user must ensure that the power supply, IOV_{DD} , reaches a stable 2.7 V minimum level by this time. Likewise, on power-down, the internal POR holds the part in reset until V_{DD} drops below 2.40 V.

Figure 63 illustrates the operation of the internal POR in detail.
