**Pin Description**

Pin Name	DESCRIPTION
CK0, 1, 2, 3 (input pins)	CK is the master clock input to this pin. The other input signals are referred at CK rising edge.
CKE0 (input pin)	This pin determines whether or not the next CK is valid. If CKE is High, the next CK rising edge is valid. If CKE is Low, the next CK rising edge is invalid. This pin is used for power-down and clock suspend modes.
$\overline{S0}, 2$ (input pins)	When $\overline{S}$ is Low, the command input cycle becomes valid. When $\overline{S}$ is high, all inputs are ignored. However, internal operations (bank active, burst operations, etc.) are held.
$\overline{RAS}$ , $\overline{CAS}$ and $\overline{WE}$ (input pins)	Although these pin names are the same as those of conventional DRAMs, they function in a different way. These pins define operation commands (read, write, etc.) depending on the combination of their voltage levels. For details, refer to the command operation section.
A0 ~ A11 (input pins)	Row address (AX0 to AX11) is determined by A0 to A11 level at the bank active command cycle CK rising edge. Column address is determined by A0 to A9 level at the read or write command cycle CK rising edge. And this column address becomes burst access start address. A10 defines the precharge mode. When A10 = High at the precharge command cycle, both banks are precharged. But when A10 = Low at the precharge command cycle, only the bank that is selected by BA0 is precharged.
BA0,1 (input pin)	BA0,1 are bank select signal. If BA0 is Low and BA1 is High, bank 0 is selected. If BA0 is High and BA1 is Low, bank 1 is selected. If BA0 is Low and BA1 is High, bank 2 is selected. If BA0 is High and BA1 is High, bank 3 is selected.
DQ0 ~ DQ63 CB0 ~ CB7 (I/O pins)	Data is input and output from these pins. These pins are the same as those of a conventional DRAMs. Data is not latched in the register.
DQMB0 ~ DQMB7 (input pins)	DQMB controls input/output buffers. Read operation: If DQMB is High, The output buffer becomes High-Z. If the DQMB is Low, the output buffer becomes Low-Z. Write operation: If DQMB is High, the previous data is held (the new data is not written). If DQMB is Low, the data is written.
V <sub>cc</sub>	3.3 V is applied. (V <sub>cc</sub> is for the internal circuit)
V <sub>ss</sub>	Ground is connected. (V <sub>ss</sub> is for the internal circuit)
REGE (register enable pin)	If REGE input is high, permits the DIMM to operate in `registered mode`. If REGE input is low, permits the DIMM to operate in `buffered mode`.
NC	No Connection pins.

Input low voltage	V <sub>IL</sub>	-0.3	0.8	V	1,3

Notes : 1. All voltage referred to V<sub>SS</sub>.

2. V<sub>IH</sub> (max) = 5.6V for pulse width ≤ 3ns

3. V<sub>IL</sub> (min) = -2.0V for pulse width ≤ 3ns

### Registered DIMM Operation

1. All control and address signals are registered on-DIMM register and hence delayed by one cycle in arriving at the SDRAMs. But data is not registered in the register.
2. CAS latency defines the delay from when a READ command is registered on a rising clock edge to when the data from that READ command becomes available at the outputs. Do not confuse DIMM CAS latency with the SDRAM CAS latency which is one clock less.

- Notes :
1. AC measurement assumes  $t_r = 1ns$ . Reference level for timing of input signals is 1.40V. If  $t_r$  is longer than 1ns, transition time compensation should be considered.
  2. Access time is measured at 1.40V. Load condition is  $C_L = 50pF$  without termination.
  3.  $t_{LZ}(min)$  defines the time at which the outputs achieves the low impedance state.
  4.  $t_{HZ}(max)$  defines the time at which the outputs achieves the high impedance state.
  5.  $t_{CES}$  define CKE setup time to CKE rising edge except Power down exit command.
  6. The on-DIMM PLL must be given enough clock cycles to stabilize ( $t_{STAB}$ ) before any operation can be guaranteed.
