

MA2909/11

RADIATION HARD MICROPROGRAM SEQUENCER

The MA2909/11 Microprogram Sequencer is fully compatible with the industry standard 2909A and 2911A components, and forms part of the GPS 2900 Series of devices. The series offers a building block approach to microcomputer and controller design, with each device in the range being expandable to permit efficient emulation of any microcode machine.

The devices have tristate outputs and have an internal address register, with all internal registers changing state on LOW to HIGH clock transition.

The 4-bit slice can cascade to any number of microwords. Branch input for N-way branches is supported. Additional features include:

- 4-bit cascadable microprogram counter.
- 4 x 4 file with stack counter supporting nesting microsubroutines.
- Zero input for returning to the zero microcode word.
- Individual OR input for each bit for branching to higher microinstructions (2909 only).

The 2909 is a 4-bit wide address controller intended for sequencing through a series of microinstructions contained in a ROM or PROM. Two 2909s may be interconnected to generate an 8-bit address (256 words), and three may be used to generate a 12-bit address (4K words).

The 2909 can select an address from any of four sources:

- 1) A set of external direct inputs (D);
- 2) External data from the R inputs, stored in an internal register;
- 3) A four-word push/pop stack; or
- 4) A program counter register (which usually contains the last address plus one).

The push/pop stack includes certain control lines so that it can efficiently execute nested subroutine linkages. Each of the four outputs can be OR'ed with an external input for conditional skip or branch instructions, and a separate line forces the outputs to all zeroes. The outputs are three-state.

The 2911 is an identical circuit to the 2909 except the four OR inputs are removed and the D and R inputs are tied together.

FEATURES

- Fully Compatible with Industry Standard 2909A and 2911A Components
- Radiation Hard CMOS SOS Technology
- High SEU Immunity
- High Speed / Low Power
- Fully TTL Compatible

Figure 1: Microprogram Sequencer Block Diagram

The 2909/2911 are CMOS SOS microprogram sequencers intended for use in high-speed microprocessor applications. The device is a cascadable 4-bit slice such that two devices allow addressing of up to 256 words of microprogram and three devices allow addressing of up to 4K words of microprogram. A detailed logic diagram is shown in figure 1.

The device contains a four input multiplexer that is used to select either the address register, direct inputs, microprogram counter, or file as the source of the next microinstruction address. This multiplexer is controlled by the S0 and S1 inputs.

The address register consists of four D-type, edge triggered flip-flops with a common clock enable. When the address register enable is LOW, new data is entered into the register on the clock LOW-to-HIGH transition. The address register is available at the multiplexer as a source for the next microinstruction address. The direct input is a 4-bit field of inputs to the multiplexer and can be selected as the next microinstruction address. On the 2911 the direct inputs are also used as inputs to the register. This allows an N-way branch where N is any word in the microcode.

The 2909/2911 contains a microprogram counter (μ PC) that is composed of a 4-bit incrementer followed by a 4bit register. The incrementer has carry-in (C_n) and carry-out ($C_n + 4$) such that cascading to larger word lengths is straight forward. The μ PC can be used in either of two ways. When the least significant carry-in to the incrementer is HIGH, the microprogram register is loaded on the next clock cycle with the current Y output word plus one ($Y + 1 \rightarrow \mu$ PC). Thus sequential microinstructions can be executed. If this least significant C_n is LOW, the incrementer passes the Y output word unmodified and the microprogram register is loaded with the same Y word on the next clock cycle ($Y \rightarrow \mu$ PC). Thus, the same microinstruction can be executed any number of times by using the 4x4 file (stack). The file is used to provide return address linkage when executing microsubroutines. The file contains a built-in stack pointer (SP) which always points to the last file word written. This allows stack reference operations (looping) to be performed without a push or pop.

The stack pointer operates as an up/down counter with separate push/pop and file enable inputs. When the file enable input is LOW and the push/pop input is HIGH, the PUSH operation is enabled. This causes the stack pointer to increment and the file to be written with the required return linkage - the next microinstruction address following the subroutine jump which initiated the PUSH.

If the file enable input is LOW and the push/pop control is LOW, a POP operation occurs. This implies the usage of the return linkage during this cycle and thus a return from subroutine. The next LOW-to-HIGH clock transition causes the stack pointer to decrement. If the file enable is HIGH, no action is taken by the stack pointer regardless of any other input.

The stack pointer linkage is such that any combination of push, pop or stack references can be achieved. One microinstruction subroutine can be performed. Since the stack is 4 words deep, up to four microsubroutines can be nested.

The ZERO input is used to force the four outputs to the binary zero state. When the ZERO input is LOW all Y outputs are LOW regardless of any other inputs (except OE). Each Y output bit also has a separate OR input such that a conditional logic one can be forced at each Y output. This allows jumping to different microinstructions on programmed conditions.

The 2909/2911 feature three-state Y outputs. These can be particularly useful in designs requiring external equipment to provide automatic checkout of the microprocessor. The internal control can be placed in the high impedance state and preprogrammed.

MULTIPLEXER SELECT CODES

Table 1 lists the select codes for the multiplexer. The two bits applied from the microword register (and additional combinational logic for branching) determine which data source contains the address for the next microinstruction. The contents of the selected source will appear on the Y outputs. Table 1 also shows the truth table for the output control and for the control of the push/pop stack. Table 2 shows in detail the effect of S_0 , S_1 , FE and PUP on the 2909. These four signals define the address that appears on the Y outputs and what the state of all the internal registers will be following the clock LOW-to-HIGH edge. In this illustration, the microprogram counter is assumed to contain initially some word J, the address register some word K, and the four words in the push/pop stack contain R_a through R_d .

Table 2: Output and Internal Next-Cycle Register States for 2909/2911

Table 3 (Page 5) illustrates the execution of a subroutine using the 2909. The configuration of Figure 2 is assumed. The instruction being executed at any given time is the one contained in the microword register (μ WR). The contents of the μ WR also control (indirectly, perhaps) the four signals S0, S1, FE, and PUP. The starting address of the subroutine is applied to the D inputs of the 2909 at the appropriate time.

In the column on the left is the sequence of microinstructions to be executed. At address J+2, the sequence control portion of the microinstruction contains the command "Jump to subroutine at A".

At the time T₂, this instruction is in the μ WR, and the 2909 inputs are set-up to execute the jump and save the return address. The subroutine address A is applied to the D inputs from the μ WR and appears on the Y outputs. The first instruction of the subroutine, I(A), is accessed and is at the inputs of the μ WR. On the next clock transition, I(A) is loaded into the μ WR for execution, and the return address J + 3 is pushed on to the stack. The return instruction is executed at T₅. Table 4 is a similar timing chart showing one subroutine linking to a second, the latter consisting of only one microinstruction.

RADIATION TOLERANCE

Total Dose Radiation Testing

For product procured to guaranteed total dose radiation levels, each wafer lot will be approved when all sample devices from each lot pass the total dose radiation test.

The sample devices will be subjected to the total dose radiation level (Cobalt-60 Source), defined by the ordering code, and must continue to meet the electrical parameters specified in the data sheet. Electrical tests, pre and post irradiation, will be read and recorded.

GEC Plessey Semiconductors can provide radiation testing compliant with MIL-STD-883 test method 1019, Ionizing Radiation (Total Dose).

Total Dose (Function to specification)*	3x10 ⁵ Rad(Si)
Transient Upset (Stored data loss)	5x10 ¹⁰ Rad(Si)/sec
Transient Upset (Survivability)	>1x10 ¹² Rad(Si)/sec
Neutron Hardness (Function to specification)	>1x10 ¹⁵ n/cm ²
Single Event Upset**	1x10 ⁻¹⁰ Errors/bit day
Latch Up	Not possible

* Other total dose radiation levels available on request

** Worst case galactic cosmic ray upset - interplanetary/high altitude orbit
