Note 1: Programmable pull-up resistor of Port 0 is specified in nibble units (P00 to P03, P04 to P07).

Note: To reduce V_{DD} signal noise and to increase the duration of the backup battery supply, V_{SS1} , V_{SS2} , and V_{SS3} should connect to each other and they should also be grounded.

Example 1: During backup in hold mode, port output 'H' level is supplied from the back-up capacitor.

Example 2: During backup in hold mode, output is not held high and its value is unsettled.

Conversion time calculation formulas:

12-bits AD Converter Mode: TCAD (Conversion time) = ((52/(division ratio))+2) × (1/3) × tCYC

8-bits AD Converter Mode: TCAD (Conversion time) = ((32/(division ratio))+2) × (1/3) × tCYC

Note 6-1: The quantization error (±1/2LSB) must be excluded from the absolute accuracy. The absolute accuracy must be measured in the microcontroller's state in which no I/O operations occur at the pins adjacent to the analog input channel.

Note 6-2: The conversion time refers to the period from the time an instruction for starting a conversion process till the time the conversion results register(s) are loaded with a complete digital conversion value corresponding to the analog input value.

The conversion time is 2 times the normal-time conversion time when:

- The first AD conversion is performed in the 12-bit AD conversion mode after a system reset.
- The first AD conversion is performed after the AD conversion mode is switched from 8-bit to 12-bit conversion mode.

The oscillation stabilization time refers to the time interval that is required for the oscillation to get stabilized after VDD goes above the operating voltage lower limit (see Figure 4).

It is recommended to insert feedback resistor(Rf: 1MΩ) when power supply voltage is used around 2.5V.

Characteristics of a Sample Subsystem Clock Oscillator Circuit

Given below are the characteristics of a sample subsystem clock oscillation circuit that are measured using a SANYO-designated oscillation characteristics evaluation board and external components with circuit constant values with which the oscillator vendor confirmed normal and stable oscillation.

The oscillation stabilization time refers to the time interval that is required for the oscillation to get stabilized after the instruction for starting the subclock oscillation circuit is executed and to the time interval that is required for the oscillation to get stabilized after the HOLD mode is reset (see Figure 4).

Note: The components that are involved in oscillation should be placed as close to the IC and to one another as possible because they are vulnerable to the influences of the circuit pattern.
