## FEATURES

Low RDS ${ }_{\text {on }}$ of $12 \mathrm{~m} \Omega$
Low input voltage range: 1.8 V to 5.5 V
3 A continuous operating current at $70^{\circ} \mathrm{C}$
1.2 V logic compatible enable input

Low $18 \mu \mathrm{~A}$ quiescent current, $\mathrm{V}_{\mathrm{IN}}<3 \mathrm{~V}$
Low $30 \mu \mathrm{~A}$ quiescent current, $\mathrm{V}_{\mathrm{IN}}=5 \mathrm{~V}$
Overtemperature protection
Ultralow shutdown current: <1 $\mu \mathrm{A}$
Ultrasmall $1.0 \mathrm{~mm} \times 1.5 \mathrm{~mm}$, 6-ball, 0.5 mm pitch WLCSP

## APPLICATIONS

## Mobile phones

## Digital cameras and audio devices

## Portable and battery-powered equipment

## GENERAL DESCRIPTION

The ADP197 is a high-side load switch designed for operation between 1.8 V and 5.5 V . This load switch provides power domain isolation, helping extended power domain isolation. The device contains a low on-resistance, N -channel MOSFET that supports more than 3 A of continuous current and minimizes power loss. The low $18 \mu \mathrm{~A}$ quiescent current and ultralow shutdown current make the ADP197 ideal for battery-operated portable equipment. The built-in level shifter for enable logic makes the ADP197 compatible with many processors and GPIO controllers.

TYPICAL APPLICATIONS CIRCUIT

Figure 1.

Overtemperature protection circuitry activates if the junction temperature exceeds $125^{\circ} \mathrm{C}$, thereby protecting itself and downstream circuits from potential damage.

In addition to operating performance, the ADP197 occupies minimal printed circuit board (PCB) space with an area of less than $1.5 \mathrm{~mm}^{2}$ and a height of 0.60 mm .

The ADP197 is available in an ultrasmall, $1 \mathrm{~mm} \times 1.5 \mathrm{~mm}$, 6 -ball, 0.5 mm pitch WLCSP.

## ABSOLUTE MAXIMUM RATINGS

Table 2.

| Parameter | Rating |
| :--- | :--- |
| VIN to GND | -0.3 V to +6.5 V |
| VOUT to GND | -0.3 V to V IN |
| EN to GND | -0.3 V to V IN |
| Continuous Drain Current |  |
| $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ | $\pm 4 \mathrm{~A}$ |
| $\mathrm{~T}_{\mathrm{A}}=85^{\circ} \mathrm{C}$ | $\pm 2.22 \mathrm{~A}$ |
| Continuous Diode Current | -50 mA |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Operating Junction Temperature Range | $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$ |
| Soldering Conditions | JEDEC J-STD-020 |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ADP197

## THEORY OF OPERATION

Figure 23. Functional Block Diagram
The ADP197 is a high-side NMOS load switch, controlled by an internal charge pump. The APD197 is designed to operate with power supply voltages between 1.8 V and 5.5 V .
An internal charge pump biases the NMOS switch to achieve a relatively constant, ultralow on resistance of $12 \mathrm{~m} \Omega$ across the entire input voltage range. The use of the internal charge pump also allows for controlled turn-on times. Turning the NMOS switch
on and off is controlled by the enable input, EN, which is capable of interfacing directly with 1.8 V logic signals.
The ADP197 is capable of 3 A of continuous current as long as $\mathrm{T}_{\mathrm{J}}$ is less than $70^{\circ} \mathrm{C}$. At $85^{\circ} \mathrm{C}$, the rated current drops to 2.22 A .
The overtemperature protection circuit activates if the load current causes the junction temperature to exceed $125^{\circ} \mathrm{C}$. When this occurs, the overtemperature protection circuitry disables the output until the junction temperature falls below approximately $110^{\circ} \mathrm{C}$, at which point the output is reenabled. If the fault condition persists, the output cycles off and on until the fault is removed.
ESD protection structures are shown in the block diagram as Zener diodes.

The ADP197 is a low quiescent current device with a nominal $4 \mathrm{M} \Omega$ pull-down resistor on its enable pin (EN). The package is a space-saving $1.0 \mathrm{~mm} \times 1.5 \mathrm{~mm}, 6$-ball WLCSP.

## APPLICATIONS INFORMATION

## CAPACITOR SELECTION

## Output Capacitor

The ADP197 is designed for operation with small, space-saving ceramic capacitors but functions with most commonly used capacitors when the effective series resistance (ESR) value is carefully considered. The ESR of the output capacitor affects the response to load transients. A typical $1 \mu \mathrm{~F}$ capacitor with an ESR of $0.1 \Omega$ or less is recommended for good transient response. Using a larger value of output capacitance improves the transient response to large changes in load current.

## Input Bypass Capacitor

Connecting at least $1 \mu \mathrm{~F}$ of capacitance from VIN to GND reduces the circuit sensitivity to the printed circuit board (PCB) layout, especially when high source impedance or long input traces are encountered. When greater than $1 \mu \mathrm{~F}$ of output capacitance is required, increase the input capacitor to match it.

## GROUND CURRENT

The major source for ground current in the ADP197 is the internal charge pump for the FET drive circuitry. Figure 24 shows the typical ground current when $\mathrm{V}_{\mathrm{EN}}=\mathrm{V}_{\mathrm{IN}}$, and varies from 1.8 V to 5.5 V .

Figure 24. Ground Current vs. Load Current, Different Input Voltages (VIN)

## ENABLE FEATURE

The ADP197 uses the EN pin to enable and disable the VOUT pin under normal operating conditions. As shown in Figure 25, when a rising voltage ( $\mathrm{V}_{\mathrm{EN}}$ ) on the EN pin crosses the active threshold, VOUT turns on. When a falling voltage ( $\mathrm{V}_{\mathrm{en}}$ ) on the EN pin crosses the inactive threshold, VOUT turns off.

Figure 25. Typical EN Operation
As shown in Figure 25, the EN pin has hysteresis built into it. This prevents on/off oscillations that can occur due to noise on the EN pin as it passes through the threshold points.
The EN pin active/inactive thresholds derive from the VIN voltage; therefore, these thresholds vary with the changing input voltage. Figure 26 shows the typical EN active/inactive thresholds when the input voltage varies from 1.8 V to 5.5 V .

Figure 26. Typical EN Thresholds vs. Input Voltage (VIN)

## TIMING

Turn-on delay is defined as the interval between the time that $\mathrm{V}_{\mathrm{EN}}$ exceeds the rising threshold voltage and when Vout rises to $\sim 10 \%$ of its final value. The ADP197 includes circuitry that has a typical 1 ms turn-on delay and a controlled rise time to limit the VIN inrush current. As shown in Figure 27 and Figure 28, the turnon delay is nearly independent of the input voltage.

## ADP197

Figure 27. Typical Turn-On Delay Time with $V_{I N}=1.9 \mathrm{~V}, I_{\text {LOAD }}=200 \mathrm{~mA}$

Figure 28. Typical Turn-On Delay Time with $V_{I N}=5.5 \mathrm{~V}, I_{\text {LOAD }}=220 \mathrm{~mA}$
The rise time is defined as the time it takes the output voltage to rise from $10 \%$ to $90 \%$ of Vout reaching its final value. It is dependent on the rise time of the internal charge pump.
For very large values of output capacitance, the RC time constant (where C is the load capacitance ( $\mathrm{C}_{\text {LOAD }}$ ) and R is the $\mathrm{RDS}_{\text {on }} \| \mathrm{R}_{\text {LOAD }}$ ) can become a factor in the rise time of the output voltage. Because RDSon is much smaller than $\mathrm{R}_{\text {LOAD }}$, an adequate approximation for RC is $\mathrm{RDS}_{\text {ON }} \times \mathrm{C}_{\text {LOAD. }}$. An input or load capacitor is not required for the ADP197 although capacitors can be used to suppress noise on the board.

Figure 29. Typical Rise Time and Inrush Current, $C_{L O A D}=100 \mu F, V_{I N}=1.9 \mathrm{~V}, I_{L O A D}=270 \mathrm{~mA}$

Figure 30. Typical Rise Time and Inrush Current, $C_{L O A D}=100 \mu F, V_{I N}=5.5 \mathrm{~V}, I_{L O A D}=350 \mathrm{~mA}$

The turn-off time is defined as the time it takes for the output voltage to fall from $90 \%$ to $10 \%$ of $V_{\text {out }}$ reaching its final value. It is also dependent on the RC time constant of the output capacitance and load resistance. Figure 31 shows the typical turn-off time with $\mathrm{V}_{\text {IN }}=3.6 \mathrm{~V}$, Cout $=1 \mu \mathrm{~F}$, and $\mathrm{R}_{\text {LOAD }}=18 \Omega$.

Figure 31. Typical Turn-Off Time
