

MGA-86576

1.5 – 8 GHz Low Noise GaAs MMIC Amplifier

Data Sheet

Description

Avago's MGA-86576 is an economical, easy-to-use GaAs MMIC amplifier that offers low noise and excellent gain for applications from 1.5 to 8 GHz.

The MGA-86576 may be used without impedance matching as a high performance 2 dB NF gain block. Alternatively, with the addition of a simple series inductor at the input, the device noise figure can be reduced to 1.6 dB at 4 GHz.

The circuit uses state-of-the-art PHEMT technology with self-biasing current sources, a source-follower interstage, resistive feedback, and on chip impedance matching networks.

A patented, on-chip active bias circuit allows operation from a single +5 V power supply. Current consumption is only 16 mA.

These devices are 100% RF tested to assure consistent performance.

Surface Mount Ceramic Package

Pin Connections

Features

- 1.6 dB Noise Figure at 4 GHz
- 23 dB Gain at 4 GHz
- +6 dBm P_{1dB} at 4 GHz
- Single +5 V Bias Supply

Applications

- LNA or Gain Stage for 2.4 GHz and 5.7 GHz ISM Bands
- Front End Amplifier for GPS Receivers
- LNA or Gain Stage for PCN and MMDS Applications
- C-Band Satellite Receivers
- Broadband Amplifier for Instrumentation

Attention: Observe precautions for handling electrostatic sensitive devices.

ESD Machine Model (Class A)

ESD Human Body Model (Class 0)

Refer to Avago Application Note A004R: Electrostatic Discharge Damage and Control.

MGA-86576 Applications Information

Introduction

The MGA-86576 is a high gain, broad band, low noise amplifier. The use of plated through holes or an equivalent minimal inductance grounding technique placed precisely under each ground lead at the device is highly recommended. A minimum of two plated through holes under each ground lead is preferred with four being highly suggested. A long ground path to pins 2 and 4 will add additional inductance which can cause gain peaking in the 2 to 4 GHz frequency range. This can also be accompanied by a decrease in stability. A suggested

layout is shown in Figure 7. The circuit is designed for use on 0.031 inch thick FR-4/G-10 epoxy glass dielectric material.

Printed circuit board thickness is also a major consideration. Thicker printed circuit boards dictate longer plated through holes which provide greater undesired inductance. The parasitic inductance associated with a pair of plated through holes passing through 0.031 inch thick printed circuit board is approximately 0.1 nH, while the inductance of a pair of plated through holes passing through 0.062 inch thick board is about 0.2 nH. Avago does not

recommend using the MGA-86576 MMIC on boards thicker than 0.040 inch.

The effects of inductance associated with the board material are easily analyzed and very predictable. As a minimum, the circuit simulation should consist of the data sheet S-Parameters and an additional circuit file describing the plated through holes and any additional inductance associated with lead length between the device and the start of the plated through hole. To obtain a complete analysis of the entire amplifier circuit, the effects of the input and output microstriplines and bias decoupling circuits should be incorporated into the circuit file.

Device Connections V_d and RF Output (Pin 3)

RF and DC connections are shown in Figure 8. DC power is provided to the MMIC through the same pin used to obtain RF output. A 50 Ω microstripline is used to connect the device to the following stage or output connector. A bias decoupling network is used to feed in V_{dd}

Figure 7. Layout for MGA-86576 Demonstration Amplifier. PCB dimensions are 1.18 inches wide by 1.30 inches high.

Figure 8. Demonstration Amplifier Schematic.

while simultaneously providing a DC block to the RF signal. The bias decoupling network shown in Figure 8, consisting of resistor R1, a short length of high impedance microstripline, and bypass capacitor C1, provides the best overall performance in the 2 to 8 GHz frequency range.

The use of lumped inductors is not desired since they tend to radiate and cause undesired feedback. Moving the bypass capacitor, C1, down the microstripline towards the V_{dd} terminal, as shown in Figure 9, will improve the gain below 2 GHz by trading off some high end gain. A minimum value of $10\ \Omega$ for R1 is

Figure 9. Complete MGA-86576 Demonstration Amplifier.

recommended to de-Q the bias decoupling network, although $100\ \Omega$ will provide the highest circuit gain over the entire 1.5 to 8 GHz frequency range. V_{dd} will have to be increased accordingly for higher values of R1. For operation in the 2 to 6 GHz frequency range, a $10\ \text{pF}$ capacitor may be used for DC blocking on the output microstripline. A larger value such as $27\ \text{pF}$ is more appropriate for operation at 1.5 GHz.

Ground (Pins 2 and 4)

Ground pins should attach directly to the backside ground plane by the shortest distance possible using the design hints suggested in the earlier section. Liberal use of plated through vias is recommended.

RF Input (Pin 1)

A $50\ \Omega$ microstripline can be used to feed RF to the device. A blocking capacitor in the $10\ \text{pF}$ range will provide a suitable DC block in the 2 to 6 GHz frequency range. Although there is no voltage present at pin 1, it is highly suggested that a DC blocking capacitor be used to prevent accidental application of a voltage from a previous amplifier stage. With no further input matching, the MGA-86576 is capable of noise figures as low as 2 dB in the 2 to 6 GHz frequency range. Since Γ_o is not $50\ \Omega$, it is possible to design and implement a very simple matching network in order to improve noise figure and input return loss over a narrow frequency range. The circuit board layout shown in Figure 7 provides an option for tuning for a low noise match anywhere in the 1.5 to 4 GHz frequency range. For optimum noise figure performance in the 4 GHz frequency range, L1 can be a 0.007 inch diameter wire 0.080 inches in length as shown in Figure 9. Alternatively, L1 can be replaced by a 0.020 inch wide microstripline whose length can be adjusted for minimum noise figure in the 1.5 to 4 GHz frequency range.

Table 1 provides the approximate inductor length for minimum noise figure at a given frequency for the circuit board shown in Figure 7.

Table 1. L1 Length vs. Frequency for Optimum Noise Figure.

Frequency GHz	Length Inches
1.5	0.70
1.8	0.60
2.1	0.50
2.4	0.40
2.5	0.30
3.0	0.20
3.7	0.10
4.0	0.05

7 Volt Bias for Operation at Higher Temperatures

The MGA-86576 was designed primarily for 5 volt operation over the -25 to $+50^\circ\text{C}$ temperature range. For applications requiring use to $+85^\circ\text{C}$, a 7 volt bias supply is recommended to minimize changes in gain and noise figure at elevated temperature. Figure 10 shows typical gain, noise figure, and output power performance over temperature at 4 GHz with 7 volts applied. With a 7 volt bias supply, output power is increased approximately 1.5 dB. Other parameters are relatively unchanged from 5 volt data. S-parameter and noise parameter data for 7 volts are available upon request from Avago.

Figure 10. Gain, NF₅₀, and P_{1dB} vs. Temperature at 4 GHz with 7 Volt Bias Supply.

Printed Circuit Board Materials

Most commercial applications dictate the need to use inexpensive epoxy glass materials such as FR-4 or G-10. Unfortunately the losses of this type of material can become excessive above 2 GHz. As an example, a 0.5 inch long 50 Ω microstripline etched on FR-4 along with a blocking capacitor has a measured loss of 0.35 dB at 4 GHz. The 0.35 dB loss adds directly to the noise figure of the MGA-86576. The use of a low loss PTFE based dielectric material will preserve the inherent low noise of the MGA-86576.
