

Preliminary Technical Data

Digital MEMS Vibration Sensor w/ Embedded RF Transceiver

ADIS16000/ADIS16229

FEATURES

Wireless vibration system, 862MHz – 928MHz
Clear Channel Assessment/Packet collision avoidance
Error Detection and Correction in RF protocol
Programmable RF Output power

Gateway node (ADIS16000)

SPI to RF function

Manage up to 6 sensor nodes

Sensor Node (ADIS16229)

Dual-axis, ±18g MEMS accelerometer
5.5kHz Resonant frequency

Digital range settings: 0 g to 1 g/5 g/10 g/20 g

Sample rate up to 20kSPS

Programmable wake-up capture, update cycle times

FFT, 512-point, real valued

Rectangular, Hanning, flat top window options

Programmable decimation filter, 11 rate settings

Multi-record capture for selected filter settings

Manual capture mode for time domain data collection

Programmable FFT averaging: up to 255 averages

Record Storage: 14 FFT records on all three axes (x, y)

Programmable alarms, 6 spectral bands, 2 levels

Adjustable response delay to reduce false alarms

Internal self-test with status flags

Digital temperature and power supply measurements

Identification registers: serial number, device ID, user ID

47mm x 38mm PCB package with SMA antenna interface

Single-supply operation: 3.0 V to 3.6 V

Operating temperature range: -40°C to +85°C

APPLICATIONS

Vibration analysis
Condition monitoring
Machine health
Instrumentation, diagnostics
Safety shutoff sensing

GENERAL DESCRIPTION

The ADIS16000 and ADIS16229 enable creation of a simple wireless vibration-sensing network for a wide variety of industrial-equipment applications. The ADIS16000 provides the gateway function, which manages the network, while the ADIS16229 provides the remote sensing function.

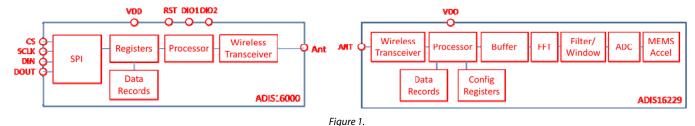

The ADIS16229 iSesnor is a complete wireless vibration sensor node that combines dual-axis acceleration sensing with advanced time domain and frequency domain signal processing. Time domain signal processing includes a programmable decimation filter and selectable windowing function. Frequency domain processing includes a 512-point, real-valued FFT, FFT magnitude averaging, and programmable spectral alarms. The FFT record storage system offers users the ability to track changes over time and capture FFTs with multiple decimation filter settings.

The ADIS16229's dynamic range, bandwidth, sample rate and noise performance are well suited for a wide variety of machine health and production equipment monitoring systems. This devices also provides a number of wireless configuration parameters enable a wide level of flexibility in managing the trade-off between battery life and communication frequency.

The ADIS16000 SPI interface provides simple connectivity with most embedded processor platforms and the SMA connector interface enables the use of many different antennas. This module supports up to six ADIS16229 devices at one time, using a proprietary wireless protocol.

Both ADIS16000 and ADIS16229 modules are in in 47.0x37.6x22.6mm PCB structures, have an SMA connector for simple antenna connection, have two mounting holes for simple installation and support operation over a temperature range of 40°C to $+85^{\circ}\text{C}$. The ADIS16000 also includes a standard 1mm, 14-pin connector for connecting to an embedded processor system. The ADIS16229 provides a lead structure that enables simple connection with standard batteries.

Preliminary Technical Data

- ¹ The maximum range depends on the frequency of vibration.
- ² Assumes that frequency flatness calibration is enabled.
- ³ The digital I/O signals are 5 V tolerant.
- ** Industrial Posignals are 3 v tolerant.

 **Indurance is qualified as per JEDEC Standard 22, Method A117 and measured at -40°C, +25°C, +85°C, and +125°C.

 **Retention lifetime equivalent at junction temperature (T₃) = 85°C as per JEDEC Standard 22, Method A117. Retention lifetime depends on junction temperature.

 **The start-up times presented reflect the time it takes for data collection to begin.
- ⁷ Applies to the reset line ($\overline{RST} = 0$) and the software reset command ($\overline{GLOB_CMD}[7] = 1$). The \overline{RST} pin must be held low for at least 10 μ s.

TIMING SPECIFICATIONS

 $T_A = 25$ °C, VDD = 3.3 V, unless otherwise noted.

Table 2.

Parameter	Description	Min ¹	Тур	Max	Unit
f _{SCLK}	SCLK frequency	0.01		2.5	MHz
t _{STALL}	Stall period between data, between 16 th and 17 th SCLK	25			μs

t _{DF} , t _{DR}	DOUT rise/fall times		5	12.5	ns
t _{SFS}	CS high after SCLK edge	5			ns

¹ Guaranteed by design, not tested.

Timing Diagrams

ABSOLUTE MAXIMUM RATINGS

Table 3.

Parameter	Rating
Acceleration	
Any Axis, Unpowered	2000 <i>g</i>
Any Axis, Powered	2000 <i>g</i>
VDD to GND	−0.3 V to +3.96 V
Digital Input Voltage to GND	-0.3 V to +3.96 V
Digital Output Voltage to GND	-0.3 V to +3.96 V
Temperature	
Operating Temperature Range	−40°C to +85°C
Storage Temperature Range	−65°C to +150°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 4. Package Characteristics

Package Type	θ_{JA}	θ _{JC}	Device Weight
15-Lead Module	31°C/W	11°C/W	6.5 grams

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

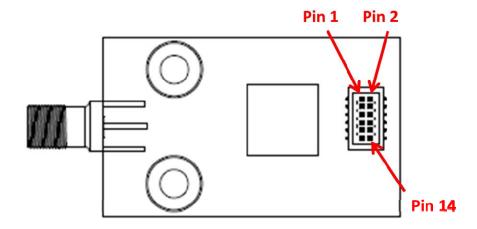

Figure 4. ADIS16000 Pin Assignments

Figure 5. Pin Configuration

Table 5. Pin Function Descriptions

Pin No.	Mnemonic	Type ¹	Description
1, 2	VDD	S	Power Supply, 3.3 V.
3, 4	GND	S	Ground.
5	DO2	I/O	Digital Input/Output Line 2.
6, 8, 9 , 10	DNC	I/O	Do not connect
7	DOUT	0	SPI, Data Output. DOUT is an output when \overline{CS} is low. When \overline{CS} is high, DOUT is in a three-
			state, high impedance mode.
9	SCLK	1	SPI, Serial Clock.
11	<u>CS</u>	1	SPI, Chip Select.
12	DIN/RXD	1	SPI, Data Input.
13	DO1	I/O	Digital Input/Output Line 1.
14	RST	1	Reset, Active Low.

¹ S is supply, O is output, I is input, and I/O is input/output.

THEORY OF OPERATION

The ADIS16000 is the "Gateway Node" and the ADIS16229 serves as the remote "Sensor Node" in a wireless vibration monitoring system. Using a proprietary wireless protocol, one ADIS16000 can support up to six ADIS16229 nodes at one time in local star network configuration (see Figure 8). As the gateway node, the ADIS16000's SPI interface provides access to an addressable register map that manages configuration parameters (gateway and sensor node), remote alarm flags and remote vibration data. The ADIS16000's SPI interface enables simple connection to most embedded processors and its standard SMA connector supports direct connection to a wide variety of antennas. The ADIS16229 only requires an antenna and battery to start-up, connect with the ADIS16000 and begin operation.

SENSING ELEMENT

Digital vibration sensing in the ADIS16229 starts with a MEMS accelerometer core on two different axes. Accelerometers translate linear changes in velocity into a representative electrical signal, using a micromechanical system like the one shown in Figure 6. The mechanical part of this system includes two different frames (one fixed, one moving) that have a series of plates to form a variable, differential capacitive network. When experiencing the force associated with gravity or acceleration, the moving frame changes its physical position with respect to the fixed frame, which results in a change in capacitance. Tiny springs tether the moving frame to the fixed frame and govern the relationship between acceleration and physical displacement. A modulation signal on the moving plate feeds through each capacitive path into the fixed frame plates and into a demodulation circuit, which produces the electrical signal that is proportional to the acceleration acting on the device.

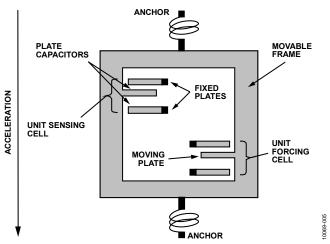

Figure 6. MEMS Sensor Diagram

SIGNAL PROCESSING

Figure 9 offers a simplified block diagram for the ADIS16229. The signal processing stage includes time-domain data capture, digital decimation/filtering, windowing, FFT analysis, FFT

averaging, and record storage. See Figure 16 for more details on the signal processing operation.

SENSOR COMMUNICATION

The ADIS16000 provides access to the ADIS16229 through dedicated pages in the register structure. When the ADIS16000 communicates with a remote ADIS16229, it copies all configuration information in these registers to their respective locations in the ADIS16229 and acquires all of the data in the ADIS16229's output registers/data records.

GATEWAY COMMUNICATION

SPI Interface

The data collection and configuration command uses the SPI, which consists of four wires. The chip select (\overline{CS}) signal activates the SPI interface, and the serial clock (SCLK) synchronizes the serial data lines. Input commands clock into the DIN pin, one bit at a time, on the SCLK rising edge. Output data clocks out of the DOUT pin on the SCLK falling edge. Since the ADIS16000 serves only as a SPI slave, the DOUT contents reflect the information requested using a DIN command.

Register organization

The ADIS16000's memory map contains 7 pages of user accessible registers, which enable simple organization of both local (gateway) and remote (sensor) functions. Each page has a page control register (PAGE_ID) address 0x00. Before accessing a register within a particular page, write that page's identification number to this register. For example, write "2" to the PAGE_ID register to access sensor node #2. Once a particular page has been "accessed," there is no need to write the same value to PAGE_ID, in order to access the rest of the registers within that page

Each 16-bit register has its own unique bit assignment and two addresses: one for its upper byte and one for its lower byte. Table 9 and Table 10 provide more details on these memory maps, which list each register, along with its function and lower byte address.

Table 6. ADIS16000 Register Map Page Organization

PAGE_ID	Function	Reference
0x0000	Gateway configuration	Table 9
0x0001	Sensor Node #1	Table 10
0x0002	Sensor Node #2	Table 10
0x0003	Sensor Node #3	Table 10
0x0004	Sensor Node #4	Table 10
0x0005	Sensor Node #5	Table 10
0x0006	Sensor Node #6	Table 10

Dual-Memory Structure

The user registers provide addressing for all input/output operations in the SPI interface. The control registers use a dual-

memory structure. The controller uses SRAM registers for normal operation, including user-configuration commands. The flash memory provides nonvolatile storage for control registers that have flash backup (see Table 9 and Table 10). When the device powers on or resets, the flash memory contents load into the SRAM, and the device starts producing data according to the configuration in the control registers. Storing configuration data in the flash memory requires a manual flash update command. For the ADIS16000, set DIN = 0x8000 (access page 0), then set DIN = 0x9240 (set GLOB_CMD[6] = 1). For a remote ADIS16229, using the following steps to update its flash: (1) turn to its page (DIN = 0x8001, to access note, for example), (2) set DIN = 0xB640 (GLOB_CMD[6] = 1), (3) set DIN = 0x8000 (turn to page 0) and (4) set DIN = 0x9202 (GLOB_CMD[8] = 1).

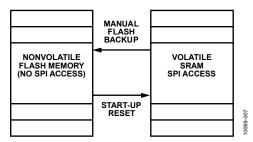

Figure 7. SRAM and Flash Memory Diagram

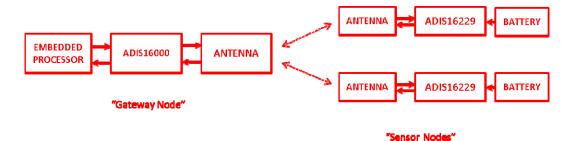

Figure 8. Star Wireless Network Example

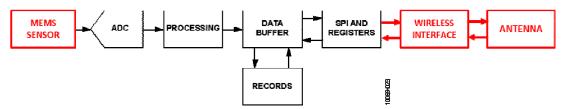

Figure 9. ADIS16229 Simplified Block Diagram

ADIS16000 BASIC OPERATION

Once it has appropriate power on the VDD pin, the ADIS16000 will automatically begin a self-initialization process. Once this process is complete, the SPI interface activates and provides access to its register structure. The SPI interface supports connectivity with most embedded processor platforms, using the connection diagram in Figure 10. The factory default configuration for DO1 provides a busy indicator signal that indicates when to avoid SPI communication requests.

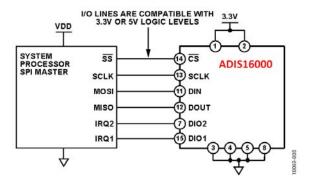

Figure 10. Electrical Hook-Up Diagram

Table 7. Generic Master Processor Pin Names and Functions

Pin Name	Function
SS	Slave select
SCLK	Serial clock
MOSI	Master output, slave input
MISO	Master input, slave output
IRQ1, IRQ2	Interrupt request inputs (optional)

The ADIS16000 SPI interface supports full duplex serial communication (simultaneous transmit and receive) and uses the bit sequence shown in Figure 14. Table 8 provides a list of the most common settings that require attention to initialize a processor serial port for the ADIS16000 SPI interface.

Table 8. Generic Master Processor SPI Settings

Tuble of Generic Maste	1 1 10000001 01 1 0000111150
Processor Setting	Description
Master	The ADIS16000 operates as a slave.
SCLK Rate ≤ 2.5 MHz	Bit rate setting.
SPI Mode 3	Clock polarity/phase
	(CPOL = 1, CPHA = 1).
MSB First	Bit sequence.
16-Bit	Shift register/data length.

Table 9 and Table 10 provide lists of user registers with their lower byte addresses. Each register consists of two bytes that each has its own unique 7-bit address. Figure 11 relates the bits of each register to their upper and lower addresses.

Figure 11. Generic Register Bit Definitions

SPI WRITE COMMANDS

User control registers govern many internal operations. The DIN bit sequence in Figure 14 provides the ability to write to these registers, one byte at a time. Some configuration changes and functions require only one write cycle. For example, set $PAGE_ID[7:0] = 1$ (DIN = 0x8001) to select Page 1 of the register map.

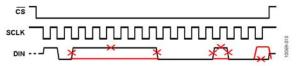

Figure 12. SPI Sequence for Selecting Page 1 for Access (DIN = 0x8001)

SPI READ COMMANDS

A single register read requires two 16-bit SPI cycles that also use the bit assignments that are shown in Figure 14. The first sequence sets $\overline{R}/W=0$ and communicates the target address (Bits[A6:A0]). Bits[D7:D0] are don't care bits for a read DIN sequence. DOUT clocks out the requested register contents during the second sequence. The second sequence can also use DIN to set up the next read. Figure 13 provides a signal diagram for all four SPI signals while reading the PROD_ID. In this diagram, DIN = 0x1600 and DOUT reflects the decimal equivalent of 16,000.

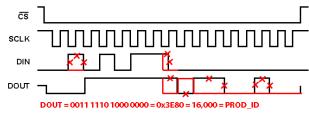

Figure 13. Example SPI Read, PROD_ID (Page 0), Second Sequence

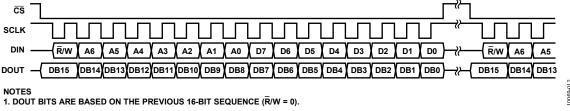

Figure 14. Example SPI Read Sequence

¹ All registers in pages 1, 2, 3, 4, 5 and 6 will read 0x0000, prior to connecting with the ADIS16229

NETWORK MANAGEMENT

Once they have an appropriate supply voltage across their VDD and GND pins, both ADIS16000 and ADIS16229 will self-initialize and prepare themselves for connecting. After completing this process, the ADIS16229 will start sending "connection requests" to any available ADIS16000 devices that are within range. The system microcontroller manages the ADIS16000's response to these requests, using the CMD_DATA (See Table 11) and GLOB_CMD registers (See Table 12), which are both in Page 0 of the ADIS16000. Adding an ADIS16229 network requires two steps: (1) write the node number (between 0 and 6) to the CMD_DATA register and then (2) set GLOB_CMD[0] = 1 (DIN = 0x9201, in page 0). After this second step, the connection process can take up to 3 minutes after writing this code. Removing a sensor from the network uses a similar two-step process: (1) write the sensor node number to the CMD_DATA register and then (2) Set $GLOB_CMD[8] = 1$ (DIN = 0x9301, page 0).

Set GLOB_CMD[1] = 1 (DIN = 0x9202) to initial an update of all of the registers, except those associated with the spectral alarms. Set GLOB_CMD[12] = 1 (DIN = 0x9310) to update all of the alarm registers, after configuring them. Separating this function will help manage the flash memory endurance.

Table 11. CMD_DATA,

Description	Execution Time
Not used	
Remove sensor node in CMD_DATA from the network	
Software reset	
Save registers to flash memory	
Flash test, compare sum of flash memory with factory value	
	Not used Remove sensor node in CMD_DATA from the network Software reset Save registers to flash memory Flash test, compare sum of flash

4	Clear DIAG_STAT register	
3	Restore factory register settings, including capture buffer and alarm registers	
2	Self-test, result in DIAG_STAT[5]	
1	Update sensor node in CMD_DATA register, in one of the manual modes	
0	Add sensor node in CMD_DATA to the network	

After connecting with an ADIS16229, the ADIS16000 will automatically copy the contents from its own NETWORK_ID[7:0] location (see Table 13) to the SENS_ID[7:0] location in the ADIS16229's page. (see Table 14).

Table 13. NETWORK_ID

Page 0, Low-Byte Address = 0x02, Read/Write

Bits	Description (Default = 0x1234)	
[15:0]	Network identification number	

The SENS_ID register will contain the value 0x0000 when not connected to a network. When connected to the network, as node 1, it will contain 0xAD34.

Table 14. SENS ID

Page 1-6, Low-Byte Address = 0x02, Read Only

[15:0]	Sensor identification

Receiver Signal Strength

The RSSI_G (see Table 15) and RSSI_S (see Table 16) provide tools for tuning the transmission power control at each location. In order to maintain effective communication, keep the transmission power high enough to maintain at least -94dBm in these registers.

Table 15. RSSI G

Page 0, Low Byte Address = 0x0A, Read Only

Bits	Description (Default = 0x)
[15:0]	Received signal strength

[15:0]	Received signal strength
	Twos complement format, 1 LSB = 1dBm
	0x0000 = 0dBm
	0xFFA2 = -94dBm

Transmission Power Control

Both ADIS16000 and ADIS16229 units provide controls for transmission power in a registers called, TX_PWR_CTRL_G (see Table 17) and TX_PWR_CTRL_S. The registers provide users with the ability to optimize the transmission power for battery optimization and to manage interference influence on other networks. Note that compliance with FCC Part 15.249 involves limiting the transmission power to -1dBm.

Table 17. TX_PWR_CTRL_G

Page 0, Low Byte Address = 0x08, Read/Write

Bits	Description (Default = 0x)
[15:5]	Not used (do not care)
[40]	Transmission power, offset binary format
	1LSB = 1.6dBm (25.5/15)
	0 = -15.5dBm (minimum)
	F = +10dBm (maximum)

Table 18. TX_PWR_CTRL_S

Page 1-6, Low Byte Address = 0x58, Read/Write

Bits	Description (Default = 0x)		
[15:5]	Not used (do not care)		
[40]	Transmission power, offset binary format		
	1LSB = 1.6dBm (25.5/15)		
	0 = -15.5dBm (minimum)		
	F = +10dBm (maximum)		

Wireless Configuration

The RF_MODE (see Table 19) register provides a number of important wireless configuration parameters. Note that when the transmission power exceeds -1dBm, FCC Part 15.247 requires the use of "frequency-hopping."

Table 19. RF_MODE

Page 0, Low Byte Address = 0x58, Read/Write

Bits	Description (Default = 0x)
[15:9]	Not used (do not care)
[8]	Complete register dump during update cycle
	(0 = enable, 1 = disable)
[7]	Periodic wake-up/beacon synchronization
	(0 = disable, 1 = enable)
[6]	Frequency hoping
	(0 = disable, 1 = enable)
[5]	Complete synchronization after missing 2 beacons
	(0 = disable, 1 = enable)
[4:2]	Not used (do not care)
[1]	Update gateway on Alarm only
	(0 = disable, 1 = enable)
[0]	Update gateway on beacon synchronization
	(0 = disable, 1 = enable)

The UPDAT_INT (See Table 20) and INT_SCL (See Table 21) registers establish the time between wake-up events, where the remote ADIS16229 captures data, analyzes it and communicates the information.

Table 20. UPDAT_INT

Page 1-6, Low Byte Address = 0x5E, Read/Write

Bits	Description (Default = 0x)	
[15:0]	Offset binary number, scale factor set by INT_SCL register	

Table 21. INT_SCL

Page 1-6, Low Byte Address = 0x60, Read/Write

Bits	Description (Default = 0x)	
[15:2]	Not used (do not care)	
[1:0]	Scale factor	
	00 = 30.52μsec/LSB, maximum = 2 seconds	
	01 = 0.488msc/LSB, maximum = 31.98 seconds	
	10 = 1/128 sec/LSB, maximum = 512 seconds	
	11 = 1 sec/LSB, maximum = 18.2 hours	

The beacon synchronization function uses periodic monitoring for drift in sensor node clocks and limits their sleep time to 30 minutes (or less) in order to maintain consistent synchronization. The BEACON_SETUP (See Table 22) register provides a user control for this function. When operating in real-time mode (REC_CTRL1 register, See Table 27) this mode is not necessary and automatically turns off.

Table 22. BEACON_SETUP

Page 0, Low Byte Address = 0x10, Read/Write

1 480 0, 20 11 2 / 10 11 41 200 011 0, 110 41 110 110 110 110 110 110 110 110		
Bits	Description (Default = 0x)	
[15:1]	Not used	
0	1 = Beacon synchronization enable	

0 = Beacon synchronization disable

The BEACON_INT (See Table 23) register sets the interval time between re-synchronizing events with the ADIS16000 (gateway).

Table 23. BEACON_INT

Page 1-6, Low Byte Address = 0x62, Read/Write

Bits	Description (Default = 0x)	
[15:0]	Offset binary number, scale factor set by INT_SCL register	

Communication Tools

The PKT_TIME_H (upper word) and PKT_TIME_L (lower word) registers provide a 32-bit timer for tracking the relative times associated with packet transmission times. This maximum value for this number is 49.71 days. At this point, the registers start over at 0x0000.

Table 24. PKT_TIME_H

Page 1-6, Low Byte Address = 0x54, Read/Write

Page 1-6, Low Byte Address = 0x52, Read/Write

Bits	Description (Default = N/A)
[15:0]	Offset binary number, lower word, 1 LSB = 1msec

The NW_ERROR_STAT (see Table 26) register provides all of the error flags associated with the wireless communication.

Table 26. NW_ERROR_STAT

Page 0, Low Byte Address = 0x06), Read/Write

1 age 0, Low Dyte Address - 0x00), Read/ Write		
Bits	Description (Default = 0x1100)	
[15:12]	Sensor node associated present error flags in this register	
[11:10]	Not used	
9	Received packet from an unknown device.	
8	Packet synchronization failure, from the most recent received packet	
7	No response from one or more sensor nodes during beacon synchronization	
6	Failed to receive a packet from the sensor node	
5	Packet length mismatch	
4	Missing packet	
3	Packets received out of SYNC	
2	Failure to receive acknowledgement from a sensor node	
1	Low signal strength from a sensor node, read RSSI_S register for power level of this signal. See Table 16	
0	CRC mismatch error associated with the most recent packet from the Sensor Node Packet	

SENSOR NODE RECORDING MODE/SIGNAL PROCESSING

The ADIS16229 provides a complete sensing system for recording and monitoring vibration data. Figure 15 provides a simplified block diagram for the signal processing associated with spectral record acquisition on both axes (x and y). User registers provide controls for data type (time or frequency), trigger mode (manual or automatic), collection mode (real time or capture), sample rates/filtering, windowing, FFT averaging, spectral alarms, and I/O management.

RECORDING MODE

The recording mode selection establishes the data type (time or frequency domain), trigger type (manual or automatic), and data collection (captured or real time). The REC_CTRL1[1:0] bits (see Table 27) provide four operating modes: manual FFT, automatic FFT, manual time capture, and real time. After setting REC_CTRL1, the manual FFT, automatic FFT, and manual time capture modes require a start command to start acquiring a spectral or time domain record. All of these modes automatically trigger when the sensor receives the configuration packet from the gateway. Set GLOB_CMD[11] = 1 to halt the operation and wait for further instructions from the ADIS16000..

Table 27. REC_CTRL1
Page 1-6, Low Byte Address = 0x1A, Read/Write

ruge 1 of Low Byte rudiess — oxiri, redui, write		
Bits	Description (Default = 0x1100)	
[15:14]	Not used (don't care).	
[13:12]	Window setting.	
	00 = rectangular, $01 = Hanning$, $10 = flat top$, $11 = N/A$.

[1:0]	Recording mode.	
	00 = manual FFT, 01 = automatic FFT,	
	10 = manual time capture, 11 = real-time sampling/data	
	access.	

Manual FFT Mode

Set REC_CTRL1[1:0] = 00 to place the device in manual FFT mode, which will result in triggering a single FFT cycle. When the spectral record is complete, the device will transmit the data to the ADIS16000 and wait for another start command.

Automatic FFT Mode

Set REC_CTRL1[1:0] = 01 to place the device in automatic FFT mode. Use the UPDAT_INT and INT_SCL registers to establish the period between "wake-up times," which triggers data capture, FFT computation and analysis.

Manual Time Capture Mode

Set REC_CTRL1[1:0] = 10 to place the device into manual time capture mode, which will result in triggering a single time domain data capture. When the device is operating in this mode, 512 samples of time domain data are loaded into the buffer for each axis. This data goes through all time domain signal processing, except the pre-FFT windowing, prior to loading into the data buffer for user access. When the data record is complete, the device will transmit the data to the ADIS16000 and wait for another start command.

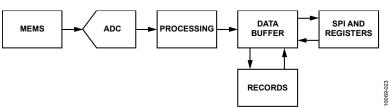

Figure 15. Simplified Block Diagram

Real-Time Mode

Set REC_CTRL1[1:0] = 11 to place the device into real-time mode. In this mode, the device samples only one axis, at a rate of 5 kSPS, and provides data on its output register at the SR0 sample rate setting in AVG_CNT[3:0] (see Table 28). Select the axis of measurement in this mode by reading its assigned register. For example, select the x-axis by reading X_BUF, using DIN = 0x1400. See Table 59 or Table 60 for more information on the x_BUF registers. No other ADIS16229 nodes will be able to communicate with the ADIS16000 when one of them is in real-time mode.

SPECTRAL RECORD PRODUCTION

The ADIS16229 produces a spectral record by taking a time record of data on both axes, then scaling, windowing, and performing an FFT process on each time record. This process repeats for a programmable number of FFT averages, with the FFT result of each cycle accumulating in the data buffer. After completing the selected number of cycles, the FFT averaging process completes by scaling the data buffer contents. Then the data buffer contents are available to the SPI and output data registers.

SAMPLE RATE/FILTERING

The sample rate for each axis is 20 kSPS. The internal ADC samples both axes in a time-interleaving pattern (x1, y1, x2, y2...) that provides even distribution of data across the data record. The averaging/decimating filter provides a control for the final sample rate in the time record. By averaging and decimating the time domain data, this filter provides the ability to focus the spectral record on lower bandwidths, which produces finer frequency resolution in each FFT frequency bin. AVG_CNT (see Table 28) provides the setting for the four different sample rate options in REC_CTRL1[11:8] (SRx, see Table 27). All four options are available when using the manual FFT, automatic FFT, and manual time capture modes. When more than one sample rate option is enabled while the device is in one of the manual modes, the device produces a spectral record for one SRx at a time, starting with the lowest number. After completing the spectral record for one SRx option, the device waits for another start command before producing a spectral record for the next SRx option that is enabled in REC_CTRL1[11:8]. When

more than one sample rate option is enabled while the device is in the automatic FFT mode, the device produces a spectral record for one SRx option, and then waits for the next automatic trigger, which occurs based on the UPDAT_INT and INT_SCL registers. See Figure 17 for more details on how multiple SRx options influence data collection and spectral record production. When in real-time mode, the output data rate reflects the SR0 setting.

Table 29 provides a list of SRx settings available in the AVG_CNT register (see Table 28), along with the resulting sample rates, FFT bin widths, bandwidth, and estimated total noise. Note that each SRx setting also has associated range settings in the REC_CTRL2 register (see Table 30) and the FFT averaging settings that are shown in the FFT_AVG1 and FFT_AVG2 registers (see Table 34 and Table 35, respectively).

Table 28. AVG_CNT
Page 1-6, Low Byte Address = 0x32, Read/Write

Bits	Description (Default = 0x9630)
[15:12]	Sample Rate Option 3, binary (0 to 10), SR3 option sample rate = $20,000 \div 2^{AVG_CNT[15:12]}$
[11:8]	Sample Rate Option 2, binary (0 to 10), SR2 option sample rate = $20,000 \div 2^{AVG_CNT[11:8]}$
[7:4]	Sample Rate Option 1, binary (0 to 10), SR1 option sample rate = $20,000 \div 2^{AVG_CNT[7:4]}$
[3:0]	Sample Rate Option 0, binary (0 to 10), SR0 option sample rate = $20,000 \div 2^{AVG_CNT[3:0]}$

Table 29. Sample Rate Settings and Filter Performance

SRx Option	Sample Rate, f _s (SPS)	Bin Width (Hz)	Bandwidth (Hz)	Peak Noise per Bin (mg)

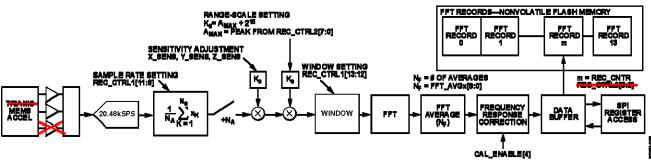

Figure 16. Signal Flow Diagram, REC_CTRL1[1:0] = 00 or 01, FFT Analysis Modes

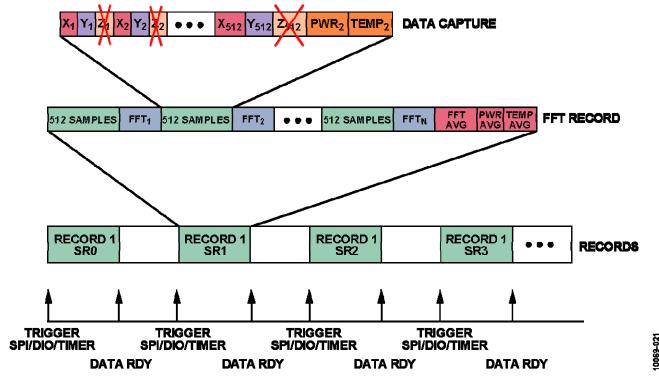

Figure 17. Spectral Record Production, with All SRx Settings Enabled

DYNAMIC RANGE/SENSITIVITY

The range of the ADIS16229 accelerometers depends on the frequency of the vibration. The accelerometers have a self-resonant frequency of 5.5 kHz, and the signal conditioning circuit applies a single-pole, low-pass filter (2.5 kHz) to the response. The self-resonant behavior of the accelerometer influences the relationship between vibration frequency and dynamic range, as shown in Figure 18, which displays the response to peak input amplitudes, assuming a sinusoidal vibration signature at each frequency. The accelerometer resonance and low-pass filter also influence the magnitude response, as shown in Figure 19.

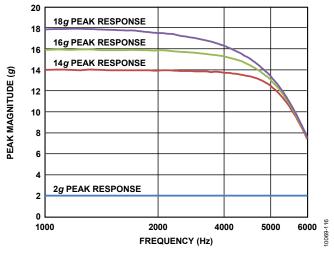

Figure 18. Peak Magnitude vs. Frequency

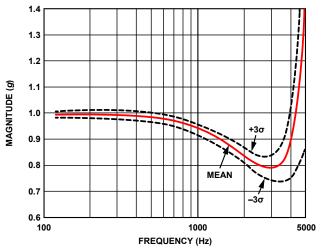

Figure 19. Magnitude/Frequency Response (CAL_ENABLE[4] = 0)

Dynamic Range Settings

REC_CTRL2 (see Table 30) provides four range settings that are associated with each sample rate option, SRx. The range options that are referenced in REC_CTRL2 reflect the maximum dynamic range, which occurs at the lower part of the frequency range and does not account for the decrease in range (see Figure 18). For example, set REC_CTRL2[5:4] = 10 (DIN = 0x9C20) to set the peak acceleration (A_{MAX}) to 10 g on the SR2 sample rate option. These settings help optimize FFT precision and sensitivity when monitoring lower magnitude vibrations. For each range setting in Table 30, this stage scales the time domain data so that the maximum value equates to 2^{15} LSBs for time domain data and 2^{16} LSBs for frequency domain data.

Note that the maximum range for each setting is 1 LSB smaller than the listed maximum. For example, the maximum number of codes in the frequency domain analysis is $2^{16} - 1$, or 65,535. For example, when using a range setting of 1 g in one of the FFT modes, the maximum measurement is equal to 1 g times $2^{16} - 1$, divided by 2^{16} . See Table 31 for the resolution associated with each setting and Figure 16 for the location of this operation in the signal flow diagram. The real-time mode automatically uses the 20 g range setting.

Table 30. REC_CTRL2

Table 31. Range Settings and LSB Weights

Range Setting (g) (REC_CTRL2[5:4])	Time Mode (mg/LSB)	FFT Mode (mg/LSB)
0 to 1	0.0305	0.0153
0 to 5	0.1526	0.0763
0 to 10	0.3052	0.1526
0 to 20	0.6104	0.3052

Scale Adjustment

The x_SENS registers (see Table 32 and Table 33) provide a fine-scale adjustment function for each axis. The following equation describes how to use measured and ideal values to calculate the scale factor for each register in LSBs:

$$SCFx = \begin{bmatrix} a_{XI} / a_{XM} - 1 \end{bmatrix} \times 2^{18}$$

where:

 a_{xt} is the ideal x-axis value.

 a_{xM} is the actual x-axis measurement.

These registers contain correction factors, which come from the factory calibration process. The calibration process records accelerometer output in four different orientations and computes the correction factors for each register.

These registers also provide write access for in-system adjustment. Gravity provides a common stimulus for this type of correction process. Use both +1 g and -1 g orientations to reduce the effect of offset on this measurement. In this case, the ideal measurement is 2 g, and the measured value is the difference of the accelerometer measurements at +1 g and -1 g orientations. The factory-programmed values are stored in flash memory and are restored by setting GLOB_CMD[3] = 1 (DIN = 0xB604) (see Table 74).

	•
Bits	Description (Default = N/A)
[15:0]	Y-axis scale correction factor (SCFy), twos complement

PRE-FFT WINDOWING

REC_CTRL1[13:12] provide three options for pre-FFT windowing of time data. For example, set REC_CTRL1[13:12] = 01 to use the Hanning window, which offers the best amplitude resolution of the peaks between frequency bins and minimal broadening of peak amplitudes. The rectangular and flat top windows are also available because they are common windowing options for vibration monitoring. The flat top window provides accurate amplitude resolution with a trade-off of broadening the peak amplitudes.

FFT

The FFT process converts each 512-sample time record into a 256-point spectral record that provides magnitude vs. frequency data.

FFT Averaging

The FFT averaging function combines multiple FFT records to reduce the variation of the FFT noise floor, which enables detection of lower vibration levels. Each SRx option in the REC_CTRL1 register has its own FFT average control, which establishes the number of FFT records to average into the final FFT record. To enable this function, write the number of averages for each SRx option that is enabled in the REC_CTRL1 register to the FFT_AVGx registers. For example, set FFT_AVG2[8:0] = 0x4A (DIN = 0x904A) to set the number of FFT averages to 16 for the SR2 sample rate option and 1024 for the SR3 sample rate option.

Table 34. FFT_AVG1

Page 0, Low Byte Address = 0x0E, Read/Write

Bits	Description (Default = 0x0108)
[15:8]	FFT averages for a single record, SR1 sample rate, N_F in Figure 16; range = 1 to 255, binary
[7:0]	FFT averages for a single record, SR0 sample rate, N_F in Figure 16; range = 1 to 255, binary

Table 35. FFT_AVG2

Page 0, Low Byte Address = 0x10, Read/Write

Bits	Description (Default = 0x0101)
[15:8]	FFT averages for a single record, SR3 sample rate, N _F in Figure 16; range = 1 to 255, binary
	FFT averages for a single record, SR2 sample rate, N _F in Figure 16; range = 1 to 255, binary

RECORDING TIMES

When using automatic FFT mode, the automatic recording period (REC_PRD) must be greater than the total recording time. Use the following equations to calculate the recording time:

Manual time mode

$$t_R = t_S + t_{PT} + t_{ST} + t_{AST}$$

FFT modes

$$t_R = N_F \times (t_S + t_{PT} + t_{FFT}) + t_{ST} + t_{AST}$$

Table 36 provides a list of the processing times and settings that are used in these equations.

Table 36. Typical Processing Times

•••			
Function	Time (ms)		
Sample Time, ts	1 ÷ f _s , per AVG_CNT		
Processing Time, t _{PT}	18.7		
FFT Time, t _{FFT}	32.7		
Number of FFT Averages, N _F	Per FFT_AVG1, FFT_AVG2		
Storage Time, t _{ST}	120.0		
Alarm Scan Time, t _{AST}	2.21		

The storage time (t_{ST}) applies only when a storage method is selected in REC_CTRL1[3:2] (see Table 27 for more details about the record storage settings). The alarm scan time (t_{AST}) applies only when the alarms are enabled in ALM_CTRL[4:0] (see Table 41 for more information). Understanding the recording time helps predict when data is available, for systems that cannot use DO1 to monitor the status of these operations. Note that when using automatic FFT mode, the automatic recording period (REC_PRD) must be greater than the total recording time.

DATA RECORDS

After the ADIS16229 finishes processing FFT data, it stores the data into the data buffer, where it is available for external access using the SPI and x_BUF registers (see Table 59 and Table 60). REC_CTRL1[3:2] (see Table 27) provides programmable conditions for writing buffer data into the FFT records, which are in nonvolatile flash memory locations. Set $REC_CTRL1[3:2] = 01$ to store data buffer data into the flash memory records only when an alarm condition is met. Set REC_CTRL1[3:2] = 10 to store every set of FFT data into the flash memory locations. The flash memory record provides space for a total of 14 records. Each record stored in flash memory contains a header and frequency domain (FFT) data from all axes (x, and y). When all 14 records are full, new records do not load into the flash memory. The REC_CNTR register (see Table 37) provides a running count for the number of records that are stored. Set GLOB_CMD[8] = 1 (DIN = 0xBF01) to clear all of the records in flash memory.

Table 37. REC_CNTR

Bits	Description (Default = 0x0000)				
[15:5]	Not used				
[4:0]	Total number of records taken; range = 0 to 14, binary				

When used in conjunction with automatic trigger mode and record storage, FFT analysis for each sample rate option requires no additional inputs. Depending on the number of FFT averages, the time between each sample rate selection may be quite large. Note that selecting multiple sample rates reduces the number of records available for each sample rate setting, as shown in Table 38.

Table 38. Available Records per Sample Rate Selected

Number of Sample Rates Selected	Available Records
1	14

SENSOR NODE SPECTRAL ALARMS

The alarm function offers six spectral bands for alarm detection. Each spectral band has high and low frequency definitions, along with two different trigger thresholds (Alarm 1 and Alarm 2) for each accelerometer axis. Table 40 provides a summary of each register used to configure the alarm function.

Table 40. Alarm Function Register Summary

Register	Address	Description			
ALM_F_LOW	0x20	Alarm frequency band, lower limit			
ALM_F_HIGH	0x22	Alarm frequency band, upper limit			
ALM_X_MAG1	0x24	X-Axis Alarm Trigger Level 1 (warning)			
ALM_Y_MAG1	0x26	Y-Axis Alarm Trigger Level 1 (warning)			
ALM_X_MAG2	0x2A	X-Axis Alarm Trigger Level 2 (fault)			
ALM_Y_MAG2	0x2C	Y-Axis Alarm Trigger Level 2 (fault)			
ALM_PNTR	0x2C	Alarm pointer			
ALM_S_MAG	0x2E	System alarm trigger level			
ALM_CTRL	0x30	Alarm configuration			
DIAG_STAT	0x34	Alarm status			
ALM_X_STAT	0x38	X-axis alarm status			
ALM_Y_STAT	0x3A	Y-axis alarm status			
ALM_X_PEAK	0x3C	X-axis alarm peak			
ALM_Y_PEAK	0x3E	Y-axis alarm peak			
ALM_X_FREQ	0x44	X-axis alarm frequency of peak alarm			
ALM_Y_FREQ	0x46	Y-axis alarm frequency of peak alarm			

The ALM_CTRL register (see Table 41) provides control bits that enable the spectral alarms of each axis, configures the system alarm, sets the record delay for the spectral alarms, and configures the clearing function for the DIAG_STAT error flags (see Table 84).

Table 41. ALM_CTRL

0	Alarm X enable (ALM_X_MAG). $1 = \text{enabled}$, $0 = \text{disabled}$.						

ALARM DEFINITION

The alarm function provides six programmable spectral bands, as shown in Figure 20. Each spectral alarm band has lower and upper frequency definitions for all of the sample rate options

(SRx). It also has two independent trigger level settings, which are useful for systems that value warning and fault condition indicators.

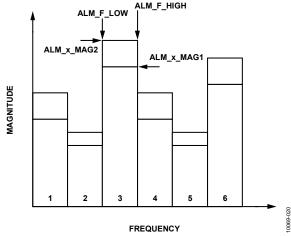

Figure 20. Spectral Band Alarm Setting Example, ALM_PNTR = 0x03

Select the spectral band for configuration by writing its number (1 to 6) to ALM_PNTR[2:0] (see Table 42). Then select the sample rate option using ALM_PNTR[9:8]. This number represents a binary number, which corresponds to the x in the SRx sample rates option associated with REC_CTRL1[11:8] (see). For example, set ALM_PNTR[7:0] = 0x05 (DIN = 0xAC05) to select Alarm Spectral Band 5, and set ALM_PNTR[15:8] = 0x02 (DIN = 0xB102) to select the SR2 sample rate option.

Table 42. ALM_PNTR

Page 1-6, Low Byte Address = 0x2C, Read/Write

Bits	Description (Default = 0x0000)				
[15:10]	Not used				
[9:8]	Sample rate option; range $= 0$ to 3 for SR0 to SR3				
[7:3]	Not used				
[2:0]	Spectral band number; range = 1 to 6				

Alarm Band Frequency Definitions

After the spectral band and sample rate settings are set, program the lower and upper frequency boundaries by writing their bin numbers to the ALM_F_LOW register (see Table 43) and ALM_F_HIGH register (see Table 44). Use the bin width definitions listed in Table 29 to convert a frequency into a bin number for this definition. Calculate the bin number by dividing the frequency by the bin width that is associated with the sample rate setting. For example, if the sample rate is 5000 Hz and the lower band frequency is 400 Hz, divide that number by the bin width of 10 Hz to arrive at the 40th bin as the lower band setting. Then set ALM_F_LOW[7:0] = 0x28 (DIN = 0xA028) to establish 400 Hz as the lower frequency for the 5000 SPS sample rate setting.

Alarm Trigger Settings

The ALM_x_MAG1 and ALM_x_MAG2 registers (see Table 45 to Table 48) provide two independent trigger settings for both axes of acceleration data. They use the data format established by the range settings in the REC_CTRL2 register (see Table 30) and recording mode in REC_CTRL1[1:0] (see Table 27). For example, when using the 0 g to 1 g mode for FFT analysis, 32,768 LSB is the closest setting to 500 mg. Therefore, set ALM_Y_MAG2 = 0x8000 (DIN = 0xAB80, 0xAA00) to set the critical alarm to 500 mg, when using the 0 g to 1 g range option in REC_CTRL2 for FFT records. See Table 30 and Table 31 for more information about formatting each trigger level. Note that trigger settings that are associated with Alarm 2 should be greater than the trigger settings for Alarm 1. In other words, the alarm magnitude settings should meet the following criteria:

ALM_X_MAG2 > ALM_X_MAG1 ALM_Y_MAG2 > ALM_Y_MAG1

Enable Alarm Settings

Before configuring the spectral alarm registers, clear their current contents by setting GLOB_CMD[9] = 1 (DIN = 0xB702). After completing the spectral alarm band definitions, save the settings by setting GLOB_CMD[12] = 1 (DIN = 0xB710). The device ignores the save command if any of these locations has already been written to.

ALARM INDICATOR SIGNALS

GPO_CTRL[5:0] (see Table 83) and ALM_CTRL[6] (see Table 41) provide controls for establishing DO1 and DO2 as dedicated alarm output indicator signals. Use GPO_CTRL[5:0] to select the alarm function for DO1 and/or DO2; then set ALM_CTRL[6] = 1 to enable DO1 to serve as an Alarm 1 indi-cator and DO2 as an Alarm 2 indicator. This setting establishes DO1 to indicate Alarm 1 (warning) conditions and DO2 to indicate Alarm 2 (critical) conditions.

ALARM FLAGS AND CONDITIONS

The FFT header (see Table 69) contains both generic alarm flags (DIAG_STAT[13:8]; see Table 84) and spectral band-specific alarm flags (ALM_x_STAT; see Table 50, Table 51). The FFT header also contains magnitude (ALM_x_PEAK; see Table 52, Table 53) and frequency information (ALM_x_FREQ; see Table 54, Table 55) associated with the highest magnitude of vibration content in the record.

ALARM STATUS

The ALM_x_STAT registers (see Table 50, Table 51) provide alarm bits for each spectral band on the current sample rate option.

Table 50. ALM_X_STAT Low Byte Address = 0x38, Read Only

Bits	Description (Default = 0x0000)

READING OUTPUT DATA

After the ADIS16229 updates the ADIS16000 with its data, it is available in the data buffer and FFT records (if selected). In manual time capture mode, the record for each axis contains 512 samples. In manual and automatic FFT mode, each record contains the 256-point FFT result for each accelerometer axis. Table 56 provides a summary of registers that provide access to processed sensor data.

Table 56. Output Data Registers

	1		•
Register		Address	Description
	TEMP_OUT	0x0A	Internal temperature
	SUPPLY_OUT	0x0C	Internal power supply
	BUF_PNTR	0x12	Data buffer index pointer
	REC_PNTR	0x14	FFT record index pointer
	X_BUF	0x06	X-axis accelerometer buffer
	Y_BUF	0x08	Y- axis accelerometer buffer
	GLOB_CMD	0x36	FFT record retrieve command
	TIME_STAMP_L	0x40	Time stamp, lower word
	TIME_STAMP_H	0x42	Time stamp, upper word
	REC_INFO1	0x4C	FFT record header information
	REC_INFO2	0x4E	FFT record header information

READING DATA FROM THE DATA BUFFER

After completing a spectral record and updating each data buffer, the ADIS16000 loads the first data sample from each data buffer into the x_BUF registers (see Table 59 and Table 60) and sets the buffer index pointer in the BUF_PNTR register (see Table 57) to 0x0000. The index pointer determines which data samples load into the x_BUF registers. For example, writing 0x009F to the BUF_PNTR register (DIN = 0x9300, DIN = 0x929F) causes the 160th sample in each data buffer location to load into the x_BUF registers. The index pointer increments with every x_BUF read command, which causes the next set of capture data to load into each capture buffer register automatically. This enables an efficient method for reading all 256 samples in a record, using sequential read commands, without having to manipulate the BUF_PNTR register.

ACCESSING FFT RECORD DATA

The FFT records can be stored in flash memory. The REC_PNTR register (see Table 58) and GLOB_CMD[13] (see Table 74) provide access to the FFT records, as shown in Figure 22. For example, set REC_PNTR[7:0] = 0x0A (DIN = 0x940A) and GLOB_CMD[13] = 1 (DIN = 0xB720) to load FFT Record 10 in the FFT buffer for SPI/register access.

DATA FORMAT

Table 59 and Table 60 list the bit assignments for the x_BUF registers. The acceleration data format depends on the range scale setting in REC_CTRL2 (see Table 30) and the recording mode settings in REC_CTRL1 (see Table 27). Table 61 provides some data formatting examples for the FFT mode, and Table 62 offers some data formatting examples for the16-bit, twos complement format used in manual time mode.

Table 59. X_BUF Low Byte Address = 0x06, Read Only

REAL-TIME DATA COLLECTION

When using real-time mode, select the output channel by reading the associated x_BUF register. For example, set DIN = 0x1600 to select the y-axis sensor for sampling. After selecting the channel, use the data-ready signal to trigger subsequent data reading of the Y_BUF register. In this mode, use the time domain data formatting for a range setting of $20 \ g$, as shown in Table 31.

POWER SUPPLY/TEMPERATURE

At the end of each spectral record, the ADIS16229 also measures power supply and internal temperature. It accumulates a 5.12 ms record of power supply measurements at a sample rate of 50 kHz and takes 64 samples of internal temperature data over a period of 1.7 ms. The average of the power supply and internal tempera-ture loads into the SUPPLY_OUT register (see

Table 64 and Table 65) and the TEMP_OUT registers (See

Table 66 and Table 67), respectively. When using real-time mode, these registers update only when this mode starts.

FFT EVENT HEADER

Each FFT record has an FFT header that contains information that fills all of the registers listed in Table 69. The information in these registers contains recording time, record configuration settings, status/error flags, and several alarm outputs. The registers listed in Table 69 update with every record event and also update with record-specific information when using GLOB_CMD[13] (see Table 74) to retrieve a data set from the FFT record in flash memory.

Table 69. FFT Header Register Information

Register	Address	Description	
DIAG_STAT	0x34	Alarm status	
ALM_X_STAT	0x38	X-axis alarm status	
ALM_Y_STAT	0x3A	Y-axis alarm status	
ALM_X_PEAK	0x3C	X-axis alarm peak	
ALM_Y_PEAK	0x3E	Y-axis alarm peak	
TIME_STMP_L	0x40	Time stamp, lower word	
TIME_STMP_H	0x42	Time stamp, upper word	
ALM_X_FREQ	0x44	X-axis alarm frequency of peak alarm	
ALM_Y_FREQ	0x46	Y-axis alarm frequency of peak alarm	
REC_INFO1	0x4C	FFT record header information	
REC_INFO2	0x4E	FFT record header information	

The REC_INFO1 register (see Table 70) and the REC_INFO2 register (see Table 71) capture the settings associated with the current FFT record.

Table 70. REC_INFO1

[15:0]	Record time stamp, high integer, binary, seconds	

SYSTEM TOOLS

GLOBAL COMMANDS

The GLOB_CMD register (see Table 74) provides an array of single-write commands for convenience. Setting the assigned bit to 1 activates each function. When the function completes, the bit restores itself to 0. For example, clear the capture buffers by setting GLOB_CMD[8] = 1 (DIN = 0xB701). All of the commands in the GLOB_CMD register require that the power supply be within normal limits for the execution times listed in Table 74.

Table 74. GLOB_CMD

Page 1-6, Low Byte Address = 0x36, Write Only

Bits	Description	Execution Time
15	Clear autonull correction	35 μs
14	Retrieve spectral alarm band information from the ALM_PNTR setting	40 μs
13	Retrieve record data from flash memory	1.9 ms
12	Save spectral alarm band registers to SRAM	461 μs
11	Record start/stop	N/A
10	Set BUF_PNTR = 0x0000	36 µs
9	Clear spectral alarm band registers from flash memory	25.8 ms
8	Clear records	25.9 ms
7	Software reset	52 ms
6	Save registers to flash memory	29.3 ms
5	Flash test, compare sum of flash memory with factory value	5 ms
4	Clear DIAG_STAT register	36 μs
3	Restore factory register settings and clear the capture buffers	84 ms
2	Self-test, result in DIAG_STAT[5]	32.9 ms
1	Power-down	N/A
0	Autonull	822 ms

STATUS/ERROR FLAGS

Critical system error flags are in the DIAG_STAT register for each ADIS16229. These flags indicate various error or alarm conditions that may influence system performance. Multiple flags in these registers can be high at one time and the flags will persist (go high again, after clearing) when the error conditions continue to exist. The flags in bits 0 through 6 will remain in a latch condition, until clearing the problem or clearing (using Use GLOB_CMD[4]). The Alarm flags (upper byte) will latch if ALM_CTRL[7] = 1 (See Table 41)

0	Power supply < 3.125 V		

SELF-TEST

Set GLOB_CMD[2] = 1 (DIN = 0xBE02) (see Table 74) to run an automatic self-test routine, which reports a pass/fail result to DIAG_STAT[5] (see Table 84).

FLASH MEMORY MANAGEMENT

Set GLOB_CMD[5] = 1 (DIN = 0xB620) to run an internal checksum test on the flash memory, which reports a pass/fail result to DIAG_STAT[6]. The FLASH_CNT register (see Table 85) provides a running count of flash memory write cycles. This is a tool for managing the endurance of the flash memory. Figure 23 quantifies the relationship between data retention and junction temperature.
