

## DESCRIPTION

The MP1906 is a high-performance, 80V, gate driver that can drive two external N-MOSFETs in a half-bridge configuration with a 12V gate supply. It accepts independent gate input signals and provides shoot-through prevention. During under-voltage lockout, the output of the high- and low-side drivers goes low to prevent erratic operation under low supply conditions.

The high-current driving capability and short dead time make it suitable for high-power and high-efficiency power applications, such as telecom DC-DC converters. The compact 8-pin SOIC package minimizes the component count and the board space.

## FEATURES

- Drives Two Low-Cost, High-Efficiency N-MOSFETs
- 10V-16V Gate Drive Supply
- 3.3V, 5V Logic Compatibility
- 80ns Propagation Delay
- Less than 90µA Quiescent Current
- Under-Voltage Lockout for Both Channels
- Input-Signal-Overlap Protection
- Internal 150ns Dead Time
- Available in a Compact 8-pin SOIC Package

## APPLICATIONS

- Motor Drivers
- Half-Bridge Power Supplies
- Avionics DC-DC Converters
- Active-Clamp Forward Converters

All MPS parts are lead-free and adhere to the RoHS directive. For MPS green status, please visit MPS website under Products, Quality Assurance page.

**Notes:**

- Exceeding these ratings may damage the device.
- The maximum allowable power dissipation is a function of the maximum junction temperature  $T_J$  (MAX), the junction-to-ambient thermal resistance  $\theta_{JA}$ , and the ambient temperature  $T_A$ . The maximum allowable continuous power dissipation at any ambient temperature is calculated by  $P_D$  (MAX) =  $(T_J$  (MAX)- $T_A$ )/ $\theta_{JA}$ . Exceeding the maximum allowable power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- The device is not guaranteed to function outside of its operating conditions.
- Measured on JESD51-7, 4-layer PCB.

## PIN FUNCTIONS

Pin #	Name	Description
1	VCC	Supply Input. Supplies power to all internal circuitry. Requires a decoupling capacitor to ground placed close to this pin to ensure a stable and clean supply.
2	HPWM	Logic input for high-side gate driver output.
3	LPWM	Logic input for low-side gate driver output. Active low.
4	GND	Ground.
5	BG	Gate Driver Output for low-side MOSFET.
6	SW	Source Return for high-side MOSFET.
7	TG	Gate Driver Output for high-side MOSFET.
8	BT	Bootstrap. Internal power supply pin for high-side floating driver. Add a 1 $\mu$ F ceramic bootstrap capacitor from BT to SW pin.

## OPERATION

### Switch Shoot-through Protection

The input signals of HPWM and LPWM are independently controlled. Input shoot-through protection circuitry prevents shoot-through between the TG and BG outputs. Only one of the FET drivers can be on at one time. If HPWM is high and LPWM is low, both TG and BG are OFF.

### Under Voltage Lockout

When  $V_{CC}$  or  $V_{BT}$  goes below their respective UVLO threshold, both BG and TG outputs will go low to both FETS. Once  $V_{CC}$  and  $V_{BT}$  rises above the UVLO threshold, both TG and BG will stay low until there is a rising edge on either HPWM or LPWM.

Figure 3 shows the operation of the TG and BG under different HPWM and LPWM and UVLO conditions.

## APPLICATION INFORMATION

### Reference Design Circuits Half Bridge Motor Driver

In a half-bridge converter topology, the MOSFET-driving signals have a dead time: HPWM and LPWM driven with alternating signals from the

PWM controller. The input voltage can be up to 80V in this application.

Figure 4: Half-Bridge Motor Driver

### Active-Clamp-Forward Converter

An active-clamp-forward-converter topology alternately drives the MOSFETs. The high-side MOSFET and the capacitor,  $C_{RESET}$ , reset the

power transformer in a lossless manner. This topology runs well at duty cycles exceeding 50%. However, the input voltage may not run at 80V.
