1.0 INTRODUCTION

The US16MY02AA VFD module is an integrated display module utilizing the 16-MY-02GK single row 16 digit alphanumeric VFD. An on board converter supplies the DC and AC voltages necessary to drive the VFD. Display driver circuitry provides character generation for 64 characters as well as 32 dimming levels. Control of the module is via a simple synchronous serial interface.

4.0 FUNCTIONAL DESCRIPTION

Input data from the host system is loaded into the module's display buffer via the serial data input channel. The internal timing and control system synchronizes the signal and digit output signals to provide correct timing for the multiplexing operation. A 16 x 64 bit programmable logic array (PLA) is provided for segment decoding of the full upper-case ASCII character set. Input data from the host system is loaded as a series of 8-bit data bytes clocked in on the high to low transition of the clock.

Control and Character Data Bytes

The most significant bit (bit 7) is loaded first and is referred to as the control bit (C-bit). If the C-bit of any byte is logical 1, the byte is a control data byte; if it is logical 0, the byte is a character data byte. The functions and formats of control and character data bytes are described in detail below.

4.1 WRITING CONTROL DATA BYTES

When the C-bit of the loaded byte is logical 1, bits 6 and 5 are decoded into one of three control commands, while data associated with the command function is decoded from bits 4 to 0. The three display functions controlled by bits 7 to 4 are tabulated below (note: the duty cycle control byte uses bits 7 to 5).

8-BIT CONTROL BYTE 7 6 5 4 3 2 1 0	FUNCTION
1 0 1 0 X X X X	Load Buffer Pointer (position of character to be defined)
1 1 0 0 Y Y Y Y	Load Digit Counter (number of characters to be displayed)
1 1 1 Z Z Z Z Z	Load Duty Cycle (luminance level control)

- NOTES:
1. "XXXX" - 4 bit binary value of the digit position to be written to.
 2. "YYYY" - 4 bit binary value of the number of characters to be displayed.
 3. "ZZZZZ" - 5 bit binary value divided 31 times 100% equals luminance level.

4.1.1 BUFFER POINTER

The buffer pointer control byte requires bits 7,6,5 and 4 to be set to 1010, respectively. This allows any specific character within the display to be modified. The character to be modified is represented by the value of bits 3 to 0, the actual value being the decimal value of the position minus 2. If no buffer pointer control byte is specified, the controller will default to position 1. For a complete list of buffer pointer values see the table below.

Hex byte	Pointer Value	Character Controlled
A0	0	2
A1	1	3
A2	2	4
A3	3	5
A4	4	6
A5	5	7
A6	6	8
A7	7	9
A8	8	10
A9	9	11
AA	10	12
AB	11	13
AC	12	14
AD	13	15
AE	14	16
AF	15	1

For example, to point to character position number 7, a decimal value of 5 is entered; hence, the 8-bit byte would be:

4.1.2 DIGIT COUNTER

The digit counter control byte requires bits 7,6,5 and 4 to be set to 1100, respectively. This is used to define the number of character positions to be controlled. This byte is normally used only during initialization routines. The binary value of the data corresponding to bits 3 thru 0 determines the actual number of characters to be controlled. When all 16 characters are to be controlled, bits 3 thru 0 should be set to 0. If less than 16 characters are used, a number corresponding to the actual number of characters to be controlled should be entered.

For example, if six characters are to be controlled, the full 8 bit byte would be:

4.1.3 DUTY CYCLE COUNTER CONTROL

The duty cycle control byte requires bits 7,6, and 5 to be set to 111, respectively. The value of the data corresponding to the remaining bits determines the luminance level of the display.

The duty cycle control byte contains a five bit numeric field (bits 4 to 0) that allows the 'on' time for all digits to be modified. Luminance levels are available in 1/31 or 3.2% steps. A binary value of 31 represents maximum luminance, while a value of 0 places the output drivers into the "off" state and blanks the display.

For example, a binary value of 24 would force the display's luminance level to be 77% of maximum luminance, and the full 8-bit byte would be:

4.2 WRITING CHARACTER DATA BYTES

Character data bytes are loaded into the data buffer as 8 bit bytes, with the C-bit (bit 7) set to 0. The 64 available data bytes are shown in Figure 6 on page 13, with their corresponding ASCII characters.

The display buffer pointer is automatically incremented before each character data byte is stored. Decimal points and commas will not cause the buffer pointer to increment, and are therefore always associated with the character data byte previously entered.

If it is desirable to place characters out of sequence, that is not from position 1 to 16, then each character data byte must be preceded by the appropriate positional data through the use of the buffer pointer control byte.

4.3 POWER-ON RESET

Once Vcc has stabilized after power up, a 100us active low pulse must be applied to the RESET\ input to initialize the module. The following conditions are established after a RESET\ pulse has been applied.

- 1) The duty cycle is set to 0 (this blanks the display).
- 2) The digit counter is set to 16 characters.
- 3) The buffer pointer is set to point to the left most character (position 1).
