#### **①** PRECAUTION AGAINST ESD FOR SEMICONDUCTORS

#### Note:

Strong electric field, when exposed to a MOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop generation of static electricity as much as possible, and quickly dissipate it once, when it has occurred. Environmental control must be adequate. When it is dry, humidifier should be used. It is recommended to avoid using insulators that easily build static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work bench and floor should be grounded. The operator should be grounded using wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions need to be taken for PW boards with semiconductor devices on it.

#### **②** HANDLING OF UNUSED INPUT PINS FOR CMOS

#### Note:

No connection for CMOS device inputs can be cause of malfunction. If no connection is provided to the input pins, it is possible that an internal input level may be generated due to noise, etc., hence causing malfunction. CMOS devices behave differently than Bipolar or NMOS devices. Input levels of CMOS devices must be fixed high or low by using a pull-up or pull-down circuitry. Each unused pin should be connected to VDD or GND with a resistor, if it is considered to have a possibility of being an output pin. All handling related to the unused pins must be judged device by device and related specifications governing the devices.

#### **③** STATUS BEFORE INITIALIZATION OF MOS DEVICES

#### Note:

Power-on does not necessarily define initial status of MOS device. Production process of MOS does not define the initial operation status of the device. Immediately after the power source is turned ON, the devices with reset function have not yet been initialized. Hence, power-on does not guarantee out-pin levels, I/O settings or contents of registers. Device is not initialized until the reset signal is received. Reset operation must be executed immediately after power-on for devices having reset function.

- The information contained in this document is being issued in advance of the production cycle for the product. The parameters for the product may change before final production or NEC Electronics Corporation, at its own discretion, may withdraw the product prior to its production.
- Not all products and/or types are available in every country. Please check with an NEC Electronics sales representative for availability and additional information.
- No part of this document may be copied or reproduced in any form or by any means without the prior written consent of NEC Electronics. NEC Electronics assumes no responsibility for any errors that may appear in this document.
- NEC Electronics does not assume any liability for infringement of patents, copyrights or other intellectual property rights of third parties by or arising from the use of NEC Electronics products listed in this document or any other liability arising from the use of such products. No license, express, implied or otherwise, is granted under any patents, copyrights or other intellectual property rights of NEC Electronics or others.
- Descriptions of circuits, software and other related information in this document are provided for illustrative purposes in semiconductor product operation and application examples. The incorporation of these circuits, software and information in the design of a customer's equipment shall be done under the full responsibility of the customer. NEC Electronics assumes no responsibility for any losses incurred by customers or third parties arising from the use of these circuits, software and information.
- While NEC Electronics endeavors to enhance the quality, reliability and safety of NEC Electronics products, customers agree and acknowledge that the possibility of defects thereof cannot be eliminated entirely. To minimize risks of damage to property or injury (including death) to persons arising from defects in NEC Electronics products, customers must incorporate sufficient safety measures in their design, such as redundancy, fire-containment and anti-failure features.
- NEC Electronics products are classified into the following three quality grades: "Standard", "Special" and "Specific". The "Specific" quality grade applies only to NEC Electronics products developed based on a customer-designated "quality assurance program" for a specific application. The recommended applications of an NEC Electronics products depend on its quality grade, as indicated below. Customers must check the quality grade of each NEC Electronics product before using it in a particular application.
  - "Standard": Computers, office equipment, communications equipment, test and measurement equipment, audio and visual equipment, home electronic appliances, machine tools, personal electronic equipment and industrial robots.
  - "Special": Transportation equipment (automobiles, trains, ships, etc.), traffic control systems, anti-disaster systems, anti-crime systems, safety equipment and medical equipment (not specifically designed for life support).
  - "Specific": Aircraft, aerospace equipment, submersible repeaters, nuclear reactor control systems, life support systems and medical equipment for life support, etc.

The quality grade of NEC Electronics products is "Standard" unless otherwise expressly specified in NEC Electronics data sheets or data books, etc. If customers wish to use NEC Electronics products in applications not intended by NEC Electronics, they must contact an NEC Electronics sales representative in advance to determine NEC Electronics' willingness to support a given application.

(Note)

- (1) "NEC Electronics" as used in this statement means NEC Electronics Corporation and also includes its majority-owned subsidiaries.
- (2) "NEC Electronics products" means any product developed or manufactured by or for NEC Electronics (as defined above).

# **Regional Information**

Some information contained in this document may vary from country to country. Before using any NEC Electronics product in your application, please contact the NEC Electronics office in your country to obtain a list of authorized representatives and distributors. They will verify:

- · Device availability
- Ordering information
- · Product release schedule
- · Availability of related technical literature
- Development environment specifications (for example, specifications for third-party tools and components, host computers, power plugs, AC supply voltages, and so forth)
- Network requirements

In addition, trademarks, registered trademarks, export restrictions, and other legal issues may also vary from country to country.

#### INTRODUCTION

ReadersThis manual is intended for users who wish to understand the functions of the<br/>V850E/ME2 (μPD703111) to design application systems using the V850E/ME2.

 Purpose
 The purpose of this manual is for users to gain an understanding of the hardware functions of the V850E/ME2.

Organization The V850E/ME2 User's Manual is divided into two parts: Hardware (this manual) and Architecture (V850E1 Architecture User's Manual). The organization of each manual is as follows:

Hardware	

- Pin functions
- CPU function
- Internal peripheral functions
- Electrical specifications (target value)

- Data type
- Register set
- Instruction format and instruction set
- · Interrupts and exceptions
- Pipeline operation

How to Read This Manual It is assumed that the readers of this manual have general knowledge in the fields of electrical engineering, logic circuits, and microcontrollers.

- To find the details of a register where the name is known
   →Refer to APPENDIX A REGISTER INDEX.
- To understand the details of an instruction function
   →Refer to the V850E1 Architecture User's Manual.

To know the electrical specifications of the V850E/ME2

- $\rightarrow$  Refer to CHAPTER 17 ELECTRICAL SPECIFICATIONS (TARGET VALUES).
- To understand the overall functions of the V850E/ME2
   →Read this manual according to the CONTENTS.
- How to interpret the register format
  - $\rightarrow$ For a bit whose bit number is enclosed in brackets, its bit name is defined as a reserved word in the device file.

#### **CHAPTER 1 INTRODUCTION**

The V850E/ME2 is a product of the NEC Electronics single-chip microcontroller "V850 Series<sup>™</sup>. This chapter gives a simple outline of the V850E/ME2.

#### 1.1 Outline

The V850E/ME2 is a 32-bit single-chip microcontroller that integrates the V850E1 CPU, which is a 32-bit RISCtype CPU core for ASIC, newly developed as the CPU core central to system LSI for the current age of system-onchip. This device incorporates cache, data RAM, instruction RAM, and various peripheral functions such as memory controllers, a DMA controller, real-time pulse unit, serial interfaces, USB function controller (USBF), and an A/D converter for realizing high-capacity data processing and sophisticated real-time control.

#### (1) V850E1 CPU

The V850E1 CPU is a CPU core that enhances the external bus interface performance of the V850 CPU, which is the CPU core integrated in the V850 Series, and has added instructions supporting high-level languages, such as C-language switch statement processing, table lookup branching, stack frame creation/deletion, and data conversion. This enhances the performance of both data processing and control. It is possible to use the software resources of the V850 CPU integrated system since the instruction codes of the V850E1 are upwardly compatible at the object code level with those of the V850 CPU.

#### (2) External memory interface function

The V850E/ME2 features various on-chip external memory interfaces including separately configured address (26 bits) and data (32 bits) buses, and SDRAM and ROM interfaces, as well as on-chip memory controllers that can be directly linked to page ROM, etc., thereby raising system performance and reducing the number of parts needed for application systems.

Also, through the DMA controller, CPU internal calculations and data transfers can be performed simultaneously with transfers to and from the external memory, so it is possible to process large volumes of image data or voice data, etc., and through high-speed execution of instructions using internal data RAM and instruction RAM, motor control, communications control and other real-time control tasks can be realized simultaneously.

#### (3) Internal instruction RAM

The instruction RAM can be accessed at high speed, in one clock, so that application programs can be executed in real time.

#### (4) A full range of middleware and development environment products

The V850E/ME2 can execute middleware such as JPEG, JBIG, MH/MR/MMR, and TCP/IP at high speed. Also, middleware that enables speech recognition, voice synthesis, and other such processing is available, and by including these middleware programs, a multimedia system can be easily realized.

A development environment system that includes an optimized C compiler, debugger, in-circuit emulator, and other elements is also available.

#### 1.6 Function Blocks

#### 1.6.1 Internal block diagram

#### 1.6.2 On-chip units

#### (1) CPU

The CPU uses five-stage pipeline control to enable single-clock execution of address calculations, arithmetic logic operations, data transfers, and almost all other instruction processing.

Other dedicated on-chip hardware, such as a multiplier (16 bits  $\times$  16 bits  $\rightarrow$  32 bits or 32 bits  $\times$  32 bits  $\rightarrow$  64 bits) and a barrel shifter (32 bits), help accelerate processing of complex instructions.

#### (2) Bus control unit (BCU)

The BCU starts the required external bus cycle based on the physical address obtained by the CPU. When an instruction is fetched from external memory area and the CPU does not send a bus cycle start request, the BCU generates a prefetch address and prefetches the instruction code. The prefetched instruction code is stored in an instruction queue in the CPU.

The BCU controls a DRAM controller (DRAMC), page ROM controller (ROMC), and DMA controller (DMAC) and performs external memory access and DMA transfer.

#### (a) SDRAM controller

The SDRAM controller generates the SDRAS, SDCAS, UUDQM, ULDQM, LUDQM, and LLDQM signals and performs access control for SDRAM.

CAS latency 1 (excluding flyby DMA transfer), 2, and 3 are supported, and the burst length is fixed to 1. A refresh function that supports the CBR refresh cycle and a dynamic self-refresh function based on an external input are also available.

#### (b) Page ROM controller (ROMC)

This controller supports accessing ROM that includes the page access function. It performs address comparisons with the immediately preceding bus cycle and executes wait control for normal access (off-page)/page access (on-page). It can handle page widths of 8 to 128 bytes.

#### (c) DMA controller (DMAC)

This controller controls data transfer between memory and I/O instead of the CPU.

There are two address modes: flyby (1-cycle) transfer, and 2-cycle transfer. There are three bus modes, single transfer, single step transfer, and block transfer.

#### (3) RAM

Instruction RAM (128 KB) and data RAM (16 KB) are provided.

The instruction RAM can be accessed in one clock from the CPU when an instruction is fetched. Its write access time depends on the BUSCLK frequency to the CS0 space and the number of wait cycles. This RAM is mapped from address 00000000H.

The data RAM can be accessed in one clock from the CPU when its data is read. It is mapped from address FFFF8000H.

#### (4) Cache

An instruction cache (8 KB) is provided.

#### (5) Interrupt controller (INTC)

This controller handles hardware interrupt requests (NMI, INTPn) from on-chip peripheral I/O and external hardware. Eight levels of interrupt priorities can be specified for these interrupt requests, and multiple-interrupt servicing control can be performed for interrupt sources (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, L1, C00, C01, C10, C11, C20, C21, C30, C31).

#### (6) Clock generator (CG)

This clock generator supplies frequencies which are 8 times the input clock (Fx) (using an on-chip PLL) as the internal system clock ( $f_{CLK}$ ). As the input clock, an external oscillator is input from pins X1 and X2.

#### (7) Real-time pulse unit (RPU)

This unit incorporates a 6-channel 16-bit timer/event counter, 4-channel 16-bit interval timer, and 2-channel 16-bit up/down counter/timer for 2-phase encoder input and can measure pulse widths or frequency and output a programmable pulse.

#### (8) Serial interfaces (SIO)

The serial interfaces consist of 3 channels divided between an asynchronous serial interface B (UARTB) and clocked serial interface 3 (CSI3). Of these 3 channels, one is alternative with UARTB and CSI3, one is fixed to CSI3, and one is fixed to UARTB.

UARTB transfers data by using the TXDn and RXDn pins (n = 0, 1).

CSI3 transfers data by using the SOn, SIn, and  $\overline{\text{SCKn}}$  pins (n = 0, 1).

In addition, a USB function controller (USBF) is also provided.

#### (9) A/D converter (ADC)

This high-speed, high-resolution 10-bit A/D converter includes 8 analog input pins. Conversion is performed using the successive approximation method.

#### (10) PWM

Two channels for PWM signal output of 16-bit resolution have been provided. By connecting an external low-pass filter, PWM output can be used as digital to analog conversion output. PWM is ideal for actuator control signals such as those in motors.

# (11) Ports

As shown below, the following ports have general-purpose port functions and control pin functions.

Port	I/O	Control Function	
Port 1	4-bit I/O	Serial interface I/O, USB clock signal input, external interrupt input	
Port 2	1-bit input, 5-bit I/O	NMI input, serial interface I/O, external interrupt input	
Port 5	6-bit I/O	DMA controller I/O, external interrupt input, real-time pulse unit I/O	
Port 6	3-bit I/O	Real-time pulse unit I/O, external interrupt input	
Port 7	6-bit I/O	DMA controller I/O, real-time pulse unit I/O, external interrupt input	
Port AL	2-bit I/O	External address bus, external interrupt input	
Port AH	10-bit I/O	External address bus	
Port DH	16-bit I/O	External data bus, external interrupt input, PWM output, real-time pulse unit I/O	
Port CS	8-bit I/O	External bus interface control signal output	
Port CT	7-bit I/O	External bus interface control signal output

- SELF: Self-refresh state when pins are connected to SDRAM

## Notes on turning on/off power

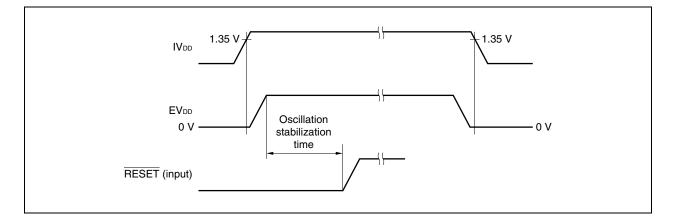

The V850E/ME2 has two power supply pins: a power supply pin for internal units ( $IV_{DD}$ ) and a power supply pin for external pins ( $EV_{DD}$ ). The I/O status of an alternate-function I/O pin may be undefined outside the range in which the operation is guaranteed. If this undefined I/O status affects the system, the pin can be made to go into a high-impedance state using the following measure.

#### • When turning on power

Keep the voltage on the  $EV_{DD}$  pin at 0 V until the voltage on the  $IV_{DD}$  pin reaches the operation guaranteed range (1.35 to 1.65 V).

## • When turning off power

Keep the voltage on the IV<sub>DD</sub> pin to within the operation guaranteed range (1.35 to 1.65 V) until the voltage on the EV<sub>DD</sub> pin drops to 0 V.

## 2.3 Description of Pin Functions

#### (1) P10 to P13 (Port 1) --- 3-state I/O

P10 to P13 function as a 4-bit I/O port that can be set to input or output in 1-bit units.

Besides functioning as an I/O port, in the control mode, these pins operate as serial interface I/O (UARTB0, CSI30), USB clock signal input, and external interrupt request input.

The operation mode can be set to port or control mode in 1-bit units, specified by the port 1 mode control register (PMC1).

#### (a) Port mode

P10 to P13 can be set to input or output in 1-bit units using the port 1 mode register (PM1).

#### (b) Control mode

P10 to P13 can be set to port/control mode in 1-bit units using the PMC1 register.

- (i) INTP10, INTP11 (Interrupt request from peripherals) ---- input These are external interrupt request input pins.
- (ii) SO0 (Serial output) --- outputThis is a serial transmit data output pin of CSI30.
- (iii) SI0 (Serial input) --- input

This is a serial receive data input pin of CSI30.

- (iv) SCK0 (Serial clock) --- 3-state I/O This is a CSI30 serial clock I/O pin.
- (v) TXD0 (Transmit data) --- output This is a serial transmit data output pin of UARTB0.

#### (vi) RXD0 (Receive data) --- input

This is a serial receive data input pin of UARTB0.

## (vii) UCLK (USB clock) ··· input

This is a clock input pin of the USB.

When using as the UCLK pin, be careful to avoid the input of a staircase waveform due to reflection, etc., or the input of noise.

\*

## (2) P20 to P25 (Port 2) --- 3-state I/O

P20 is an input-only pin. P21 to P25 function as a 5-bit I/O port that can be set to input or output in 1-bit units.

Besides functioning as an I/O port, in the control mode, these pins operate as serial interface I/O (UARTB1/CSI31) and external interrupt request input.

The operation mode can be set to port or control mode in 1-bit units, specified by the port 2 mode control register (PMC2).

# (a) Port mode

P21 to P25 can be set to input or output in 1-bit units using the port 2 mode register (PM2). P20 is an input-only port, and if a valid edge is input, it operates as an NMI input.

#### (b) Control mode

P21 to P25 can be set to port/control mode in 1-bit units using the PMC2 register.

#### (i) NMI (Non-maskable interrupt request) --- input

This is the non-maskable interrupt request input pin.

(ii) INTP21 to INTP25 (Interrupt request from peripherals) ... input These are external interrupt request input pins.

## (iii) SO1 (Serial output) --- output

This is a serial transmit data output pin of CSI31.

# (iv) SI1 (Serial input) --- input

This is a serial receive data input pin of CSI31.

#### (v) SCK1 (Serial clock) --- 3-state I/O

This is a CSI31 serial clock I/O pin.

## (vi) TXD1 (Transmit data) --- output

This is a serial transmit data output pin of UARTB1.

#### (vii) RXD1 (Receive data) ... input

This is a serial receive data input pin of UARTB1.

#### (3) P50 to P55 (Port 5) --- 3-state I/O

P50 to P55 function as a 6-bit I/O port that can be set to input or output in 1-bit units.

Besides functioning as an I/O port, in the control mode, these pins operate as DMA request input, DMA acknowledge output, DMA transfer termination output (terminal count), real-time pulse unit (RPU) I/O, and external interrupt request input.

The operation mode can be set to port or control mode in 1-bit units, specified by the port 5 mode control register (PMC5).

#### (a) Port mode

P50 to P55 can be set to input or output in 1-bit units using the port 5 mode register (PM5).

#### (b) Control mode

P50 to P55 can be set to port/control mode in 1-bit units using the PMC5 register.

#### (i) DMARQ0, DMARQ1 (DMA request) ··· input

These are DMA service request signal input pins. They correspond to DMA channels 0 and 1, respectively, and operate independently of each other. The priority order is fixed to  $\overline{\text{DMARQ0}} > \overline{\text{DMARQ1}} > \overline{\text{DMARQ2}} > \overline{\text{DMARQ2}} > \overline{\text{DMARQ3}}$ .

These signals are sampled at the rising edge of the BUSCLK signal. Maintain an active level until a DMA request is acknowledged.

## (ii) DMAAK0, DMAAK1 (DMA acknowledge) --- output

These are acknowledge signal output pins that show a DMA service request was granted. They correspond to DMA channels 0 and 1, respectively, and operate independently of each other.

In flyby transfer, these signals become active when external memory is being accessed and internal instruction RAM (in the write mode) is being accessed. When DMA transfers are being executed between internal data RAM, internal instruction RAM (in the read mode), and on-chip peripheral I/O, they do not become active.

In 2-cycle transfer, these are used as the signals to control the DMARQ0 and DMARQ1 signals.

#### (iii) TC0, TC1 (Terminal count) --- output

These are terminal count signal output pins that show that the DMA transfer from the DMA controller is complete. These pins correspond to DMA channels 0 and 1 respectively, and operate independently of each other. The terminal count signals of DMA channels 0 to 3 can be commonly output from the  $\overline{\text{TC0}}$  pin.

These signals become active for 1 clock at the rising edge of the BUSCLK signal.

#### (iv) INTPC00, INTPC01 (Interrupt request from peripherals) --- input

These are external interrupt request input pins and the external capture trigger input pins of timer C0.

#### (v) TIC0 (Timer input) --- input

This is an external count clock input pin of timer C0.

#### (vi) TOC0 (Timer output) --- output

This is a pulse signal output pin of timer C0.

## (vii) INTP50 to INTP52 (Interrupt request from peripherals) --- input

These are external interrupt request input pins.

\*

## (4) P65 to P67 (Port 6) --- 3-state I/O

P65 to P67 function as a 3-bit I/O port that can be set to input or output in 1-bit units. Besides functioning as an I/O port, in the control mode, these pins operate as real-time pulse unit (RPU) I/O and external interrupt request input.

The operation mode can be set to port or control mode in 1-bit units, specified by the port 6 mode control register (PMC6).

## (a) Port mode

P65 to P67 can be set to input or output in 1-bit units using the port 6 mode register (PM6).

#### (b) Control mode

P65 to P67 can be set to port/control mode in 1-bit units using the PMC6 register.

## (i) TIC1 (Timer input) --- input

This is the external count clock input pin for timer C1.

#### (ii) TOC1 (Timer output) --- output

This is the pulse signal output pin for timer C1.

(iii) INTP65 to INTP67 (Interrupt request from peripherals) --- input

These are external interrupt request input pins.

## (iv) INTPC10, INTPC11 (Interrupt request from peripherals) ... input

These are external interrupt request input pins and the external capture trigger input pins of timer C1.

#### (5) P72 to P77 (Port 7) --- 3-state I/O

P72 to P77 function as a 6-bit I/O port that can be set to input or output in 1-bit units.

Besides functioning as an I/O port, in the control mode, these pins operate as DMA request input, DMA acknowledge output, DMA transfer termination output (terminal count), real-time pulse unit (RPU) I/O, and external interrupt request input.

The operation mode can be set to port or control mode in 1-bit units, specified by the port 7 mode control register (PMC7).

#### (a) Port mode

P72 to P77 can be set to input or output in 1-bit units using the port 7 mode register (PM7).

## (b) Control mode

P72 to P77 can be set to port/control mode in 1-bit units using the PMC7 register.

#### (i) DMARQ2, DMARQ3 (DMA request) ... input

These are DMA service request signal input pins. They correspond to DMA channels 2 and 3, respectively, and operate independently of each other. The priority order is fixed to  $\overline{\text{DMARQ0}} > \overline{\text{DMARQ1}} > \overline{\text{DMARQ2}} > \overline{\text{DMARQ2}} > \overline{\text{DMARQ3}}$ .

These signals are sampled at the rising edge of the BUSCLK signal. Maintain an active level until a DMA request is acknowledged.

## (ii) DMAAK2, DMAAK3 (DMA acknowledge) --- output

These are acknowledge signal output pins that show a DMA service request was granted. They correspond to DMA channels 2 and 3, respectively, and operate independently of each other.

In flyby transfer, these signals become active only when external memory is being accessed and internal instruction RAM (in the write mode) is being accessed. When DMA transfers are being executed between internal data RAM, internal instruction RAM (in the read mode), and on-chip peripheral I/O, they do not become active.

In 2-cycle transfer, these are used as the signals to control the DMARQ2 and DMARQ3 signals.

## (iii) TC2, TC3 (Terminal count) --- output

These are terminal count signal output pins that show that DMA transfer from the DMA controller is complete. These pins correspond to DMA channels 2 and 3 respectively, and operate independently of each other. The terminal count signals of DMA channels 0 to 3 can be commonly output from the  $\overline{TC0}$  pin.

These signals become active for 1 clock at the rising edge of the BUSCLK signal.

#### (iv) INTPC20, INTPC21, INTPC30, INTPC31 (Interrupt request from peripherals) --- input

These are external interrupt request input pins and the external capture trigger input pins of timers C2 and C3.

## (v) TIC2, TIC3 (Timer input) --- input

These are external count clock input pins of timers C2 and C3.

## (vi) TOC2, TOC3 (Timer output) --- output

These are pulse signal output pins of timers C2 and C3.

\*

#### (6) PCM0 to PCM5 (Port CM) --- 3-state I/O

PCM0 to PCM5 function as a 6-bit I/O port that can be set to input or output in 1-bit units.

Besides functioning as a port, in the control mode, these pins operate as wait insertion signal input, bus hold control signal, refresh request signal output for SDRAM, self-refresh request signal input, and A/D converter external trigger input.

The operation mode can be set to port or control in 1-bit units, specified by the port CM mode control register (PMCCM).

#### (a) Port mode

PCM0 to PCM5 can be set to input or output in 1-bit units using the port CM mode register (PMCM).

## (b) Control mode

PCM0 to PCM5 can be set to port/control mode in 1-bit units using the PMCCM register.

#### (i) WAIT (Wait) --- input

This is the control signal input pin at which a data wait is inserted in the bus cycle. The WAIT signal can be input asynchronously to the BUSCLK signal. When the BUSCLK signal falls, sampling is executed. When the set/hold time is not terminated within the sampling timing, wait insertion may not be executed.

## (ii) HLDAK (Hold acknowledge) --- output

This is the acknowledge signal output pin that indicates the high impedance status for the address bus, data bus, and control bus when the V850E/ME2 receives a bus hold request.

While this signal is active, the impedance of the address bus, data bus, and control bus becomes high and the bus mastership is transferred to the external bus master.

#### (iii) HLDRQ (Hold request) --- input

This is the input pin through which an external device requests the V850E/ME2 to release the address bus, data bus, and control bus. The HLDRQ signal can be input asynchronously to the BUSCLK signal. When this pin is active, the address bus, data bus, and control bus are set to the high impedance status. This occurs either when the V850E/ME2 completes execution of the current bus cycle or immediately if no bus cycle is being executed, then the HLDAK signal is set as active and the bus is released.

In order to make the bus hold state secure, keep the HLDRQ signal active until the HLDAK signal is output.

#### (iv) REFRQ (Refresh request) --- output

This is the refresh request signal output pin for SDRAM.

In cases when the address is decoded by an external circuit to increase the connected SDRAM, or in cases when external SIMM's are connected, this signal is used for RAS control during the refresh cycle.

This signal becomes active during the refresh cycle. Also, during bus hold, it becomes active when a refresh request is generated and informs the external bus master that a refresh request was generated.

# (v) SELFREF (Self refresh request) ... input

This is a self-refresh request signal input pin for SDRAM.

The internal data RAM and internal instruction RAM (in the read mode) can be accessed even in the self-refresh cycle. However, access to a peripheral I/O register or external device is held pending until the self-refresh cycle is cancelled.

Caution Input to the SELFREF pin becomes valid immediately after the reset signal has been cleared. Consequently, if a low level is input to the SELFREF pin by an external pull-down resistor, self refreshing is started. Note that, at this time, the normal instruction fetch cycle does not occur.

## (vi) ADTRG (A/D trigger input) ... input

This is an external trigger input pin of the A/D converter.

#### (7) PCT0 to PCT5, PCT7 (Port CT) --- 3-state I/O

PCT0 to PCT5 and PCT7 function as a 7-bit I/O port that can be set to input or output in 1-bit units. Besides functioning as a port, in the control mode, these pins operate as control signal outputs for when memory is expanded externally.

The operation mode can be set to port or control mode in 1-bit units, specified by the port CT mode control register (PMCCT).

## (a) Port mode

PCT0 to PCT5 and PCT7 can be set to input or output in 1-bit units using the port CT mode register (PMCT).

## (b) Control mode

PCT0 to PCT5 and PCT7 can be set to port/control mode in 1-bit units using the PMCCT register.

#### (i) LLWR (Lower lower byte write strobe) --- 3-state output

This is a strobe signal output pin that shows whether the bus cycle currently being executed is a write cycle for the SRAM, external ROM, or external peripheral I/O area.

For the data bus, the lowest byte (D0 to D7) becomes valid. If the bus cycle is a lowest memory write, it becomes active at the falling edge of the BUSCLK signal in the T1 state and becomes inactive at the falling edge of the BUSCLK signal in the T2 state.

## (ii) LUWR (Lower upper byte write strobe) --- 3-state output

This is a strobe signal output pin that shows whether the bus cycle currently being executed is a write cycle for the SRAM, external ROM, or external peripheral I/O area.

For the data bus, the third byte (D8 to D15) becomes valid. If the bus cycle is a third byte memory write, it becomes active at the falling edge of the BUSCLK signal in the T1 state and becomes inactive at the falling edge of the BUSCLK signal in the T2 state.

#### (iii) ULWR (Upper lower byte write strobe) --- 3-state output

This is a strobe signal output pin that shows whether the bus cycle currently being executed is a write cycle for the SRAM, external ROM, or external peripheral I/O area.

For the data bus, the second byte (D16 to D23) becomes valid. If the bus cycle is a second byte memory write, it becomes active at the falling edge of the BUSCLK signal in the T1 state and becomes inactive at the falling edge of the BUSCLK signal in the T2 state.

## (iv) UUWR (Upper upper byte write strobe) --- 3-state output

This is a strobe signal output pin that shows whether the bus cycle currently being executed is a write cycle for the SRAM, external ROM, or external peripheral I/O area.

For the data bus, the highest byte (D24 to D31) becomes valid. If the bus cycle is a highest memory write, it becomes active at the falling edge of the BUSCLK signal in the T1 state and becomes inactive at the falling edge of the BUSCLK signal in the T2 state.

## (v) LLBE (Lower lower byte enable) --- 3-state output

This is a signal output pin that enables the lowest byte (D0 to D7) of the external data bus.

#### (vi) LUBE (Lower upper byte enable) --- 3-state output

This is a signal output pin that enables the third byte (D8 to D15) of the external data bus.

## (vii) ULBE (Upper lower byte enable) --- 3-state output

This is a signal output pin that enables the second byte (D16 to D23) of the external data bus.

#### (viii) UUBE (Upper upper byte enable) --- 3-state output

This is a signal output pin that enables the highest byte (D24 to D31) of the external data bus.

#### (ix) LLDQM (Lower lower DQ mask enable) --- 3-state output

This is a control signal output pin for the data bus to SDRAM. For the data bus, the lowest byte (D0 to D7) is valid. This signal carries out SDRAM output disable control during a read operation, and SDRAM byte mask control during a write operation.

## (x) LUDQM (Lower upper DQ mask enable) --- 3-state output

This is a control signal output pin for the data bus to SDRAM. For the data bus, the third byte (D8 to D15) is valid. This signal carries out SDRAM output disable control during a read operation, and SDRAM byte mask control during a write operation.

#### (xi) ULDQM (Upper lower DQ mask enable) --- 3-state output

This is a control signal output pin for the data bus to SDRAM. For the data bus, the second byte (D16 to D23) is valid. This signal carries out SDRAM output disable control during a read operation, and SDRAM byte mask control during a write operation.

## (xii) UUDQM (Upper upper DQ mask enable) --- 3-state output

This is a control signal output pin for the data bus to SDRAM. For the data bus, the highest byte (D24 to D31) is valid. This signal carries out SDRAM output disable control during a read operation, and SDRAM byte mask control during a write operation.

#### (xiii) RD (Read strobe) --- 3-state output

This is a strobe signal output pin that shows the bus cycle currently being executed is a read cycle for the SRAM, external ROM, external peripheral I/O, or page ROM area. In the idle state (TI), it becomes inactive.

#### (xiv) WR (Write strobe) --- 3-state output

This is a strobe signal output pin that shows the bus cycle currently being executed is a write cycle for the SRAM, external ROM, or external peripheral I/O area.

It becomes active at the falling edge of the BUSCLK signal in the T1 state and becomes inactive at the falling edge of the BUSCLK signal in the T2 state.

#### (xv) WE (Write enable) --- 3-state output

This is a enable signal output pin that shows the bus cycle currently being executed is a write cycle for the SDRAM area. In the idle state (TI), it becomes inactive.

## (xvi) BCYST (Bus cycle start timing) --- 3-state output

This is a status signal output pin that shows the start of the bus cycle. It becomes active for 1-clock cycle from the start of each cycle. In the idle state (TI), it becomes inactive.

## (8) PCS0 to PCS7 (Port CS) --- 3-state I/O

PCS0 to PCS7 function as an 8-bit I/O port that can be set to input or output in 1-bit units.

Besides functioning as a port, in the control mode, these pins operate as control signal outputs for when memory and peripheral I/O are expanded externally.

The operation mode can be set to port or control mode in 1-bit units, specified by the port CS mode control register (PMCCS).

## (a) Port mode

PCS0 to PCS7 can be set to input or output in 1-bit units using the port CS mode register (PMCS).

## (b) Control mode

PCS0 to PCS7 can be set to port/control mode in 1-bit units using the PMCCS register.

## (i) CS0 to CS7 (Chip select) --- 3-state output

These are the chip select signal output pins for the SRAM, external ROM, external peripheral I/O, and page ROM area.

The CSn signal is assigned to memory block n (n = 0 to 7).

It becomes active while the bus cycle that accesses the corresponding memory block is activated. In the idle state (TI), it becomes inactive.

## (ii) IOWR (I/O write) --- 3-state output

This is a write strobe signal output pin for external I/O during DMA flyby transfer. It indicates whether the bus cycle currently being executed is a write cycle for external I/O during DMA flyby transfer, or a write cycle for the SRAM area.

Note that if the IOEN bit of the bus cycle period control register (BCP) is set (1), this signal can be output even in the normal SRAM, external ROM, or external I/O cycle.

## (iii) IORD (I/O read) ··· 3-state output

This is a read strobe signal output pin for external I/O during DMA flyby transfer. It indicates whether the bus cycle currently being executed is a read cycle for external I/O during DMA flyby transfer, or a read cycle for the SRAM area.

Note that if the IOEN bit of the BCP register is set (1), this signal can be output even in the normal SRAM, external ROM, or external I/O cycle.

## (9) PCD0 to PCD3 (Port CD) --- 3-state I/O

PCD0 to PCD3 function as a 4-bit I/O port that can be set to input or output in 1-bit units. Besides functioning as a port, in control mode, these pins operate as control signal outputs for when the memory and peripheral I/O are expanded externally.

The operation mode can be set to port or control mode in 1-bit units, specified by the port CD mode control register (PMCCD).

## (a) Port mode

PCD0 to PCD3 can be set to input or output in 1-bit units using the port CD mode register (PMCD).

## (b) Control mode

PCD0 to PCD3 can be set to port or control mode in 1-bit units using the PMCCD register.

## (i) SDCKE (SDRAM clock enable) --- output

This is the SDRAM clock enable output signal. It becomes inactive in self-refresh and standby mode.

#### (ii) BUSCLK (Clock output) --- output

This is a clock output pin for SDRAM.

(iii) SDCAS (SDRAM column address strobe) ---- 3-state output This is a command output signal for SDRAM.

(iv) SDRAS (SDRAM row address strobe) --- 3-state output

This is a command output signal for SDRAM.

## (10) PAH0 to PAH9 (Port AH) --- 3-state I/O

PAH0 to PAH9 function as an 8- or 10-bit I/O port that can be set to input or output in 1-bit units. Besides functioning as a port, in control mode, these pins operate as an address bus (A16 to A25) for when the memory is expanded externally.

The operation mode can be set to port or control mode in 1-bit units, specified by the port AH mode control register (PMCAH).

## (a) Port mode

PAH0 to PAH9 can be set to input or output in 1-bit units using the port AH mode register (PMAH).

## (b) Control mode

PAH0 to PAH9 can be set to function alternately as A16 to A25 using the PMCAH register.

## (i) A16 to A25 (Address) --- 3-state output

These are the address output pins of the higher 10 bits of the address bus's 26-bit address when the external memory is accessed.

The output changes in synchronization with the fall of the BUSCLK signal in the T1 state. In the idle state (TI), the address of the bus cycle immediately before is retained.

## (11) PAL0, PAL1 (Port AL) --- 3-state I/O

PAL0 and PAL1 function as a 2-bit I/O port that can be set to input or output in 1-bit units. Besides functioning as a port, in control mode, these pins operate as an address bus (A0, A1) and external interrupt request input for when the memory is expanded externally.

The operation mode can be set to port or control mode in 1-bit units, specified by the port AL mode control register (PMCAL).

## (a) Port mode

PAL0 and PAL1 can be set to input or output in 1-bit units using the port AL mode register (PMAL).

## (b) Control mode

PAL0 and PAL1 can be set to port or control mode in 1-bit units using the PMCAL register.

## (i) A0, A1 (Address) --- 3-state output

These are the address output pins of the lower 2 bits of the address bus's 26-bit address when the external memory is accessed.

The output changes in synchronization with the fall of the BUSCLK signal in the T1 state. In the idle state (TI), the address of the bus cycle immediately before is retained.

# (ii) INTPL0, INTPL1 (Interrupt request from peripherals) --- input

These are external interrupt request input pins.

#### (12) PDH0 to PDH15 (Port DH) --- 3-state I/O

PDH0 to PDH15 function as an 8- or 16-bit I/O port that can be set to input or output in 1-bit units. Besides functioning as a port, in control mode, these pins operate as real-time pulse unit (RPU) I/O, PWM output, data bus (D16 to D31), and external interrupt request input.

The operation mode can be set to port or control mode in 1-bit units, specified by the port DH mode control register (PMCDH).

#### (a) Port mode

PDH0 to PDH15 can be set to input or output in 1-bit units using the port DH mode register (PMDH).

#### (b) Control mode

PDH0 to PDH15 can be set to port or control mode in 1-bit units using the PMCDH register.

- (i) INTPD0 to INTPD15 (Interrupt request from peripherals) ... input These are external interrupt request input pins.
- (ii) TOC4, TOC5 (Timer output) --- output

These are pulse signal output pins of timers C4 and C5.

(iii) INTP100, INTP101, INTP110, INTP111 (Timer capture trigger input) … input These are external capture trigger input pins of timers ENC10 and ENC11.

#### (iv) TIUD10, TIUD11 (Timer count pulse input) ... input

These are external count clock input pins of timers ENC10 and ENC11.

(v) TCUD10, TCUD11 (Timer control pulse input) ---- input These are external count clock input pins of timers ENC10 and ENC11.

#### (vi) TCLR10, TCLR11 (Timer clear) --- input

These are clear signal input pins of timers ENC10 and ENC11.

## (vii) TO10, TO11 (Timer output) --- output

These are pulse signal output pins of timers ENC10 and ENC11.

## (viii) PWM0, PWM1 (Pulse width modulation) --- output

These pins output the PWM pulse signal.

(ix) D16 to D31 (Data) --- 3-state I/O

These pins constitute a data bus for when the external memory is accessed. These are the higher 16-bit I/O bus pins of the 32-bit data. The output changes in synchronization with the rise of the BUSCLK signal in the T1 state.

#### (13) PLLSEL (PLL operating mode select) --- input

This is an input pin used to specify the PLL operating mode.

## (14) PLLV<sub>DD</sub> (PLL power supply)

This is an 1.5 V positive power supply pin for PLL synthesizer.

#### (15) PLLVss (PLL ground)

This is a ground pin for PLL synthesizer.

#### (16) SSEL0, SSEL1 (Clock generator operating mode select) --- input

These are input pins used to specify the clock generator's operating mode.

(17) JIT0, JIT1 (SSCG (spread spectrum frequency synthesizer phase locked loop) clock generator operating mode select) ... input

These are input pins used to specify the SSCG operating mode.

#### (18) DCK (Debug clock) --- input

This pin inputs a debug clock. At the rising edge of the DCK signal, the DMS and DDI signals are sampled, and data is output from the DDO pin at the falling edge of the DCK signal. Keep this pin high when the debug function is not used.

#### (19) DDI (Debug data input) --- input

This pin inputs debug data. This pin is sampled at the rising edge of the DCK signal when the debug serial interface is in the shift state. Data is input with the LSB first. Keep this pin high when the debug function is not used.

#### (20) DDO (Debug data output) --- 3-state output

This pin outputs debug data. It outputs data at the falling edge of the DCK signal when the debug serial interface is in the shift state. Data is output with the LSB first.

## (21) DMS (Debug mode select) --- input

This input pin selects a debug mode. Depending on the level of the DMS signal, the state machine of the debug serial interface changes. This pin is sampled at the rising edge of the DCK signal. Keep this pin high when the debug function is not used.

#### (22) DRST (Debug reset) --- input

This pin inputs a debug reset signal that is a negative-logic signal to initialize the DCU asynchronously. When this signal goes low, the DCU is reset/invalidated. Keep this pin low when the debug function is not used.

#### (23) MODE0, MODE1 (Mode) --- input

These are input pins used to specify the operating mode.

#### (24) RESET (Reset) ··· input

RESET is a signal that is input asynchronously and that has a constant low level width regardless of the operating clock's status. When this signal is input, a system reset is executed as the first priority ahead of all other operations.

In addition to being used for ordinary initialization/start operations, this pin can also be used to release a standby mode (HALT, IDLE, or software STOP).

## (25) X1, X2 (Crystal)

These pins are used to connect the resonator that generates the system clock.

#### (26) ANI0 to ANI7 (Analog input) ... input

#### These are analog input pins for the A/D converter.

Connect a capacitor between these pins and AVss to prevent noise-related operation faults. Also, do not apply voltage that is outside the range for AVss and AVDD to pins that are being used as inputs for the A/D converter. If it is possible for noise above the AVDD range or below the AVss to enter, clamp these pins using a diode that has a small VF value.

## (27) AVREFM, AVREFP (Analog reference voltage) --- input

These are reference voltage supply pins for the A/D converter.

#### (28) AVDD (Analog power supply)

This is a 3.3 V positive power supply pin for the A/D converter.

#### (29) AVss (Analog ground)

This is a ground pin for the A/D converter.

#### (30) EVDD (Port power supply)

This is a 3.3 V positive power supply pin for port.

## (31) EVss (Port ground)

This is a ground pin for port.

## (32) OSCVDD (Power supply for clock generator)

This is a 3.3 V positive power supply pin for the clock generator.

# (33) OSCVss (Ground for clock generator)

This is a ground pin for the clock generator.

#### (34) UVDD (Ground)

This is a 3.3 V positive power supply pin for the USB.

## (35) UDP (USB Data +) --- I/O

This is a data I/O pin (+) of the USB.

#### (36) UDM (USB Data -) --- I/O

This is a data I/O pin (-) of the USB.

#### (37) IVDD (Power supply)

These are 1.5 V positive power supply pins for each internal unit. All the IV<sub>DD</sub> pins should be connected to a positive power supply.

## (38) IVss (Ground)

These are ground pins. All the IVss pins should be grounded.

## (39) A2 to A15 (Address) --- output

These are the address output pins of the lower 14 bits of the address bus's 26-bit address when the external memory is accessed.

## (40) D0 to D15 (Data) --- 3-state I/O

These pins constitute a data bus for when the external memory is accessed. These are the lower 16-bit I/O bus pins of the 32-bit data.

The output changes in synchronization with the rise of the BUSCLK signal in the T1 state.

## (41) TRCCLK (Trace clock) --- output

This is a trace clock output pin.

# (42) TRCDATA0 to TRCDATA3 (Trace data output) --- output

These are trace data output (D0 to D3) pins.

## (43) TRCEND (Trace end status output) --- output

This is a trace end status output pin.

# 2.4 Pin I/O Circuits and Recommended Connection of Unused Pins

# 3.2 CPU Register Set

The registers of the V850E/ME2 can be classified into two categories: a general-purpose program register set and a dedicated system register set. All the registers have a 32-bit width.

For details, refer to V850E1 Architecture User's Manual.

## 3.2.1 Program register set

The program register set includes general-purpose registers and a program counter.

## (1) General-purpose registers

Thirty-two general-purpose registers, r0 to r31, are available. Any of these registers can be used as a data variable or address variable.

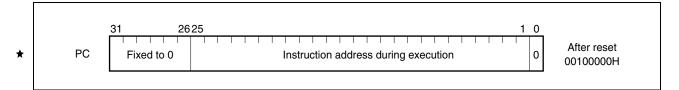

However, r0 and r30 are implicitly used by instructions, and care must be exercised when using these registers. r0 is a register that always holds 0, and is used for operations using 0 and offset 0 addressing. r30 is used, by means of the SLD and SST instructions, as a base pointer for when memory is accessed. Also, r1, r3 to r5, and r31 are implicitly used by the assembler and C compiler. Therefore, before using these registers, their contents must be saved so that they are not lost. The contents must be restored to the registers after the registers have been used. r2 may be used by the real-time OS. If the real-time OS does not use r2, it can be used as a variable register.

Name	Usage	Operation
rO	Zero register	Always holds 0
r1	Assembler-reserved register	Working register for generating 32-bit immediate data
r2	Address/data variable register	(when r2 is not used by the real-time OS)
r3	Stack pointer	Used to generate stack frame when function is called
r4	Global pointer	Used to access global variable in data area
r5	Text pointer	Register to indicate the start of the text area (where program code is located)
r6 to r29	Address/data variable register	s
r30	Element pointer	Base pointer when memory is accessed
r31	Link pointer	Used by compiler when calling function
PC	Program counter	Holds instruction address during program execution

#### Table 3-1. Program Registers

## (2) Program counter (PC)

This register holds the instruction address during program execution. The lower 26 bits of this register are valid, and bits 31 to 26 are fixed to 0. If a carry occurs from bit 25 to 26, it is ignored. Bit 0 is fixed to 0, and branching to an odd address cannot be performed.

## 3.2.2 System register set

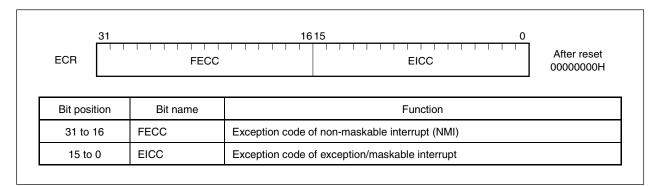

System registers control the status of the CPU and hold interrupt information.

To read/write these system registers, specify a system register number indicated below using the system register load/store instruction (LDSR or STSR instruction).

No.	System Register Name	Operand S	Operand Specification	
		LDSR Instruction	STSR Instruction	
0	Status saving register during interrupt (EIPC) <sup>Note 1</sup>	0	0	
1	Status saving register during interrupt (EIPSW)Note 1	0	0	
2	Status saving register during NMI (FEPC)	0	0	
3	Status saving register during NMI (FEPSW)	0	0	
4	Interrupt source register (ECR)	×	0	
5	Program status word (PSW)	0	0	
6 to 15	Reserved for future function expansion (operations that access these register numbers cannot be guaranteed).	×	×	
16	Status saving register during CALLT execution (CTPC)	0	0	
17	Status saving register during CALLT execution (CTPSW)	0	0	
18	Status saving register during exception/debug trap (DBPC)	O <sup>Note 2</sup>	0	
19	Status saving register during exception/debug trap (DBPSW)	O <sup>Note 2</sup>	0	
20	CALLT base pointer (CTBP)	0	0	
21	Debug interface register (DIR)	O <sup>Note 3</sup>	0	
22	Breakpoint control register 0, 1 (BPC0, BPC1)	O <sup>Note 3</sup>	O <sup>Note 3</sup>	
23	Program ID register (ASID)	0	0	
24	Breakpoint address setting register 0, 1 (BPAV0, BPAV1)	O <sup>Note 3</sup>	O <sup>Note 3</sup>	
25	Breakpoint address mask register 0, 1 (BPAM0, BPAM1)	O <sup>Note 3</sup>	O <sup>Note 3</sup>	
26	Breakpoint data setting register 0, 1 (BPDV0, BPDV1)	O <sup>Note 3</sup>	O <sup>Note 3</sup>	
27	Breakpoint data mask register 0, 1 (BPDM0, BPDM1)	O <sup>Note 3</sup>	O <sup>Note 3</sup>	
28 to 31	Reserved for future function expansion (operations that access these register numbers cannot be guaranteed).	×	×	

- **Notes 1.** Because these registers have only one set, to enable multiple interrupts, it is necessary to save these registers by program.
  - 2. These registers can be accessed only in the debug mode. If they are accessed in the user mode, the result is undefined.
  - 3. Accessing these registers in a mode other than the debug mode is prohibited.
- Caution Even if bit 0 of EIPC, FEPC, or CTPC is set to 1 by the LDSR instruction, bit 0 will be ignored when the program is returned by the RETI instruction after interrupt servicing (because bit 0 of the PC is fixed to 0). When setting the value of EIPC, FEPC, and CTPC, use an even value (bit 0 = 0) unless there is a special reason not to.
- Remark O: Access allowed
  - ×: Access prohibited

7	NP	Indicates that non-maskable interrupt (NMI) servicing is in progress. This flag set when an NMI is acknowledged, and disables multiple interrupts. 0: NMI servicing not under execution. 1: NMI servicing under execution.	
6	EP	Indicates that exception processing is in progress. This flag is set when an exception is generated. Moreover, interrupt requests can be acknowledged when this bit is set. 0: Exception processing not under execution. 1: Exception processing under execution.	
5	ID	Indicates whether a maskable interrupt request can be acknowledged or not. 0: Interrupt enabled (EI). 1: Interrupt disabled (DI).	

(2/2)

Bit position	Flag	Function
4	SAT <sup>Note</sup>	Indicates that the operation result of a saturated operation processing instruction is saturated due to overflow. Due to the cumulative flag, if the operation result is saturated by the saturation operation instruction, this bit is set (1), but is not cleared (0) even if the operation results of subsequent instructions are not saturated. To clear (0) this bit, load data in PSW. Note that in a general arithmetic operation, this bit is neither set (1) nor cleared (0). 0: Not saturated. 1: Saturated.
3	CY	This flag is set if a carry or borrow occurs as the result of an operation (if a carry or borrow does not occur, it is reset). 0: Carry or borrow does not occur. 1: Carry or borrow occurs.
2	OV <sup>Note</sup>	<ul> <li>This flag is set if an overflow occurs during operation (if an overflow does not occur, it is reset).</li> <li>0: Overflow does not occur.</li> <li>1: Overflow occurs.</li> </ul>

**Note** The result of a saturation-processed operation is determined by the contents of the OV and S flags in the saturation operation. Simply setting the OV flag (1) will set the SAT flag (1) in a saturation operation.

# 3.3 Operating Modes

## 3.3.1 Operating modes

The V850E/ME2 has the following operating modes. Mode specification is carried out using the MODE0 and MODE1 pins.

## (1) Normal operation mode

32-bit mode, 16-bit mode

After system reset is cleared, each pin related to the bus interface enters the control mode, the SRAM cycle branches to 0100000H (reset entry address) of the external device (memory), and instruction processing starts.

In the 32-bit mode, the bus interface functions as a 32-bit data bus; it functions as a 16-bit data bus in the 16-bit mode.

# Caution Be sure to allocate external memory to address 0100000H for correct operation.

## 3.3.2 Operating mode specification

The operating mode is specified according to the status of the MODE0 and MODE1 pins. In an application system fix the specification of these pins and do not change them during operation. Operation is not guaranteed if these pins are changed during operation.

MODE1	MODE0	Operating Mode		Remarks
L	L	Normal operation mode	32-bit mode	32-bit data bus
L	Н		16-bit mode	16-bit data bus

# 3.4 Address Space

# 3.4.1 CPU address space

The CPU of the V850E/ME2 is of 32-bit architecture and supports up to 4 GB of linear address space (data space) during operand addressing (data access). Also, in instruction address addressing, a maximum of 64 MB of linear address space (program space) is supported.

Figure 3-2 shows the CPU address space.

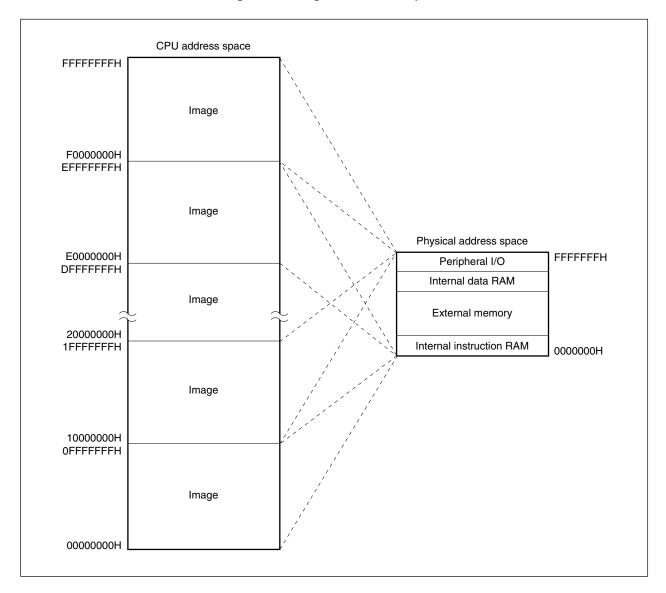

Figure	3-2.	CPU	Address	Space
--------	------	-----	---------	-------

# 3.4.2 Image

A 256 MB physical address space is seen as 16 images in the 4 GB CPU address space. In actuality, the same 256 MB physical address space is accessed regardless of the values of bits 31 to 28 of the CPU address. Figure 3-3 shows the image of the virtual addressing space.

Physical address x0000000H can be seen as CPU address 00000000H, and in addition, can be seen as address 10000000H, address 20000000H, ..., address E0000000H, or address F0000000H.

## 3.4.3 Wrap-around of CPU address space

# (1) Program space

Of the 32 bits of the PC (program counter), the higher 6 bits are fixed to 0, and only the lower 26 bits are valid. Even if a carry or borrow occurs from bit 25 to 26 as a result of a branch address calculation, the higher 6 bits ignore the carry or borrow.

Therefore, the lower-limit address of the program space, address 00000000H, and the upper-limit address 03FFFFFH become contiguous addresses. Wrap-around refers to a situation like this whereby the lower-limit address and upper-limit address become contiguous.

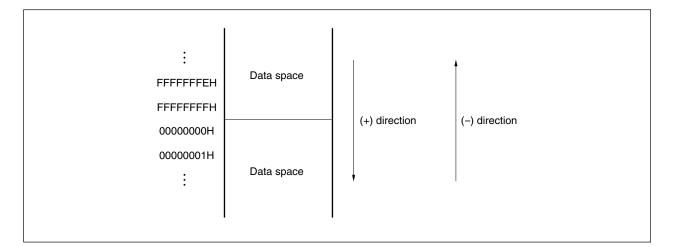

Caution The 32 KB area of 03FFF800H to 03FFFFFH can be seen as an image of 0FFFF800H to 0FFFFFFH. Instructions cannot be fetched from this area because it is an on-chip peripheral I/O area, internal data RAM area, or access-prohibited area. Therefore, do not execute any branch address calculation in which the result will reside in any part of this area.

: 03FFFFFEH 03FFFFFFH 00000000H 00000001H :	Program space Program space	(+) direction	(-) direction	
	1			

# (2) Data space

The result of an operand address calculation that exceeds 32 bits is ignored.

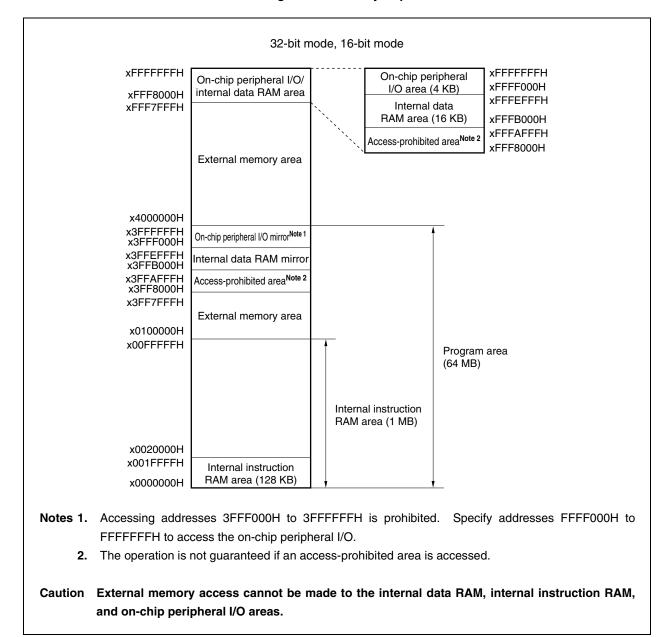

Therefore, the lower-limit address of the program space, address 00000000H, and the upper-limit address FFFFFFFH are contiguous addresses, and the data space is wrapped around at the boundary of these addresses.

# 3.4.4 Memory map

Areas are reserved in the V850E/ME2 as shown in Figure 3-4.

Figure 3-4. Memory Map

## 3.4.5 Area

#### (1) Internal instruction RAM area

### (a) Memory map

1 MB of internal instruction RAM area, addresses 00000H to FFFFFH, is reserved. 128 KB are provided at addresses 000000H to 01FFFFH as physical instruction RAM.

Caution External memory access cannot be made to addresses 020000H to FFFFFFH. If this area is accessed, the address bus (A0 to A25) outputs a low level, the data bus (D0 to D31) goes into a high-impedance state without outputting anything, and the external bus control signal becomes inactive.

# (b) Interrupt/exception table

The V850E/ME2 increases the interrupt response speed by assigning handler addresses corresponding to interrupts/exceptions.

The collection of these handler addresses is called an interrupt/exception table, which is located in the internal instruction RAM area. When an interrupt/exception request is acknowledged, execution jumps to the handler address, and the program written in that memory is executed. Table 3-3 shows the sources of interrupts/exceptions, and the corresponding addresses.

# Table 3-3. Interrupt/Exception Table (2/2)

## (2) Internal data RAM area

The 16 KB area of addresses FFFB000H to FFFEFFFH is provided as the internal data RAM area. The 16 KB area of 3FFB000H to 3FFEFFFH can be seen as an image of FFFB000H to FFFEFFFH.

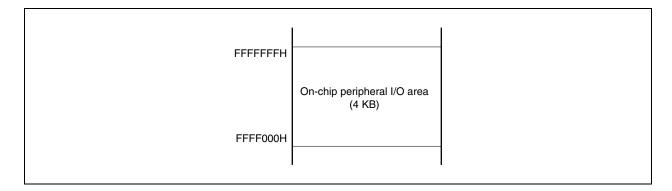

- Cautions 1. External memory access cannot be made to addresses xFFF8000H to xFFFAFFFH and x3FF8000H to x3FFAFFFH. The operation is not guaranteed if external memory access is performed.
  - 2. Do not execute the program in the internal data RAM area.

# (3) On-chip peripheral I/O area

4 KB of memory, addresses FFFF000H to FFFFFFH, are provided as an on-chip peripheral I/O area. An image of addresses FFFF000H to FFFFFFH can be seen at addresses 3FFF000H to 3FFFFFH<sup>Note</sup>.

**Note** Addresses 3FFF000H to 3FFFFFFH are access-prohibited. To access the on-chip peripheral I/O, specify addresses FFFF000H to FFFFFFH.

Peripheral I/O registers associated with the operating mode specification and the state monitoring for the onchip peripheral I/O are all memory-mapped to the on-chip peripheral I/O area. Program fetches cannot be executed from this area.

Cautions 1. For registers in which byte access is possible, if halfword access is executed, the higher 8 bits become undefined during a read operation, and the lower 8 bits of data are written to the register during a write operation.

Do not access an 8-bit register in halfword units.

Addresses that are not defined as registers are reserved for future expansion. If these
addresses are accessed, the operation is undefined and not guaranteed.
Addresses 3FFF000H to 3FFFFFFH cannot be specified as the source/destination
address of DMA transfer. Be sure to use addresses FFFF000H to FFFFFFFH for the
source/destination address of DMA transfer.

### (4) External memory area

256 MB are available for external memory area. The lower 64 MB can be used as program/data area and the higher 192 MB as data area. The external memory area is addresses x0100000H to xFDFFFFH.

Access to the external memory area is performed using the chip select signal assigned to each memory block (which is carried out in the CS unit set by chip area select control registers 0 and 1 (CSC0, CSC1)).

Note that the internal instruction RAM, internal data RAM, and on-chip peripheral I/O areas cannot be used as external memory areas.

#### 3.4.6 Recommended use of address space

The architecture of the V850E/ME2 requires that a register that serves as a pointer be secured for address generation in operand data accessing of data space. Operand data access from instruction can be directly executed at the address in this pointer register  $\pm 32$  KB. However, because the general-purpose registers that can be used as a pointer register are limited, by minimizing the deterioration of address calculation performance when changing the pointer value, the number of usable general-purpose registers for handling variables is maximized, and the program size can be saved.

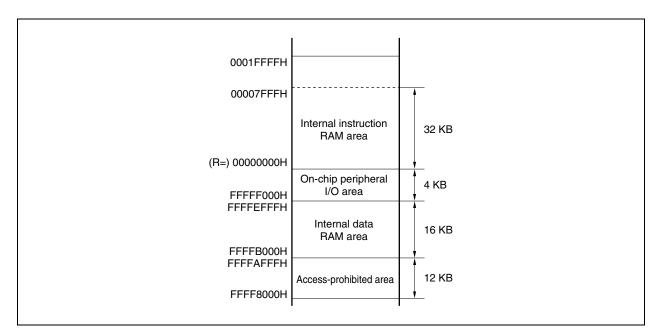

In connection with the memory map of the V850E/ME2, the following usage is recommended to enhance the efficiency of pointer operation.

#### (1) Program space

Of the 32 bits of the program counter (PC), the higher 6 bits are fixed to 0, and only the lower 26 bits are valid. Therefore, a contiguous 64 MB space, starting from address 00000000H, unconditionally corresponds to the memory map of the program space.

#### (2) Data space

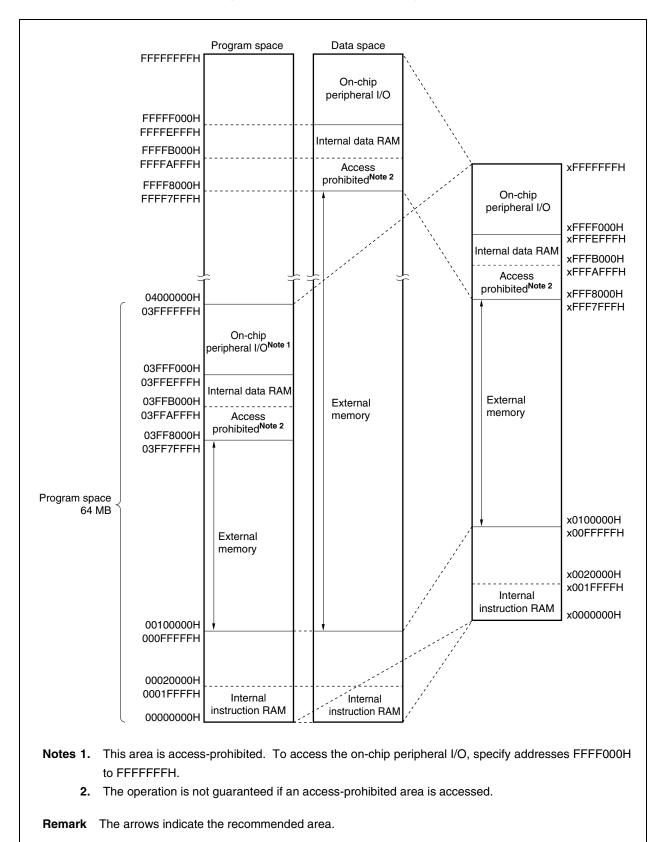

To efficiently operate the resources using wrap-around of the data space, a consecutive 16 MB are used as a data space at each of the 4 GB CPU address spaces of 00000000H to 00FFFFFFH and FF000000H to FFFFFFFH. With the V850E/ME2, a 256 MB physical address space is seen as 16 images in the 4 GB CPU address space. The highest bit (bit 25) of this 26-bit address is assigned as an address sign-extended to 32 bits.

**Example** Application of wrap-around is as shown below.

When R = r0 (zero register) is specified with the LD/ST disp16[R] instruction, an addressing range of 00000000H ±32 KB can be referenced with the sign-extended disp16.

The zero register (r0) is a register fixed to 0 by the hardware, and eliminates the need for additional registers for the pointer.

#### 3.4.8 Specific registers

Specific registers are registers that are protected from being written with illegal data due to erroneous program execution, etc. The V850E/ME2 has four specific registers, the power-save control register (PSC) (see 8.6.2 (3) Power-save control register (PSC)), clock control register (CKC) (see 8.3.1 Clock control register (CKC)), clock source select register (CKS) (see 8.3.2 Clock source select register (CKS)), and SSCG control register (SSCGC) (see 8.3.3 SSCG control register (SSCGC)). Disable DMA transfer when writing to a specific register.

There is also the command register (PRCMD), a protection register supporting write operations for specific registers to avoid an unexpected stoppage of the application system due to erroneous program execution (see **8.6.2** (2) Command register (PRCMD)).

#### 3.4.9 System wait control register (VSWC)

The system wait control register (VSWC) is a register that controls the bus access wait for the on-chip peripheral I/O registers.

Access to on-chip peripheral I/O registers is made in 3 clocks (without wait), however, in the V850E/ME2 waits may be required depending on the operation frequency. Set the values described in the table below to the VSWC in accordance with the operation frequency used.

Operation Frequency (fx)	VSWC Setting Value
10.00 MHz $\leq$ fx $\leq$ 25.00 MHz	00
25.00 MHz < fx $\leq$ 34.00 MHz	10
34.00 MHz < fx $\le$ 68.00 MHz	11
68.00 MHz < fx $\le$ 75.00 MHz	12
75.00 MHz < fx ≤ 103.00 MHz	22
103.00 MHz < fx ≤ 125.00 MHz	23
125.00 MHz < fx ≤ 150.00 MHz	33

This register can be read or written in 1-bit or 8-bit units (address: FFFFF06EH, initial value: 77H).

**Remark** If the timing of changing a count value contend with the timing of accessing a register when accessing a register having status flags that indicate the status of the on-chip peripheral functions (such as UBnSTR) or a register that indicates the count value of a timer (such as TMCn), the register access is retried. As a result, it may take a longer time to access an on-chip peripheral I/O register.

# 3.4.10 Initialization sequence

Initialize the V850E/ME2 in the following sequence.

# <1> Automatically branch to address 100000H after reset is cleared

Set the following registers that affect the external bus access performance using the program located at address 100000H. Execution automatically branches to 100000H when the reset signal is input in the power-on status.

- System wait control register (VSWC) Setting of a wait cycle for accessing the on-chip peripheral I/O
- Data wait control registers 0 and 1 (DWC0 and DWC1) Setting of a data wait cycle of the external bus
- Address setup wait control register (ASC)
   Setting of an address setup wait cycle of the external bus
- Bus cycle control register (BCC) Setting of an idle state of the external bus

As necessary, set chip area select control registers 0 and 1 (CSC0 and CSC1), bus cycle type configuration registers 0 and 1 (BCT0 and BCT1), the local bus sizing control register (LBS), the endian configuration register (BEC), line buffer control registers 0 and 1 (LBC0 and LBC1), and the page ROM configuration register (PRC).

- Cautions 1. Disable all interrupts from when the reset signal is cleared until when the program code is completely transferred to the internal instruction RAM (while steps <1> to <3> of the initialization sequence are being executed). Maskable interrupts are masked by default and do not have to be disabled.
  - 2. Set SDRAM configuration registers 1, 3, 4, and 6 (SCR1, SCR3, SCR4, and SCR6) after the processing of step <2>.

# <2> Checking LOCK bit of lock register (LOCKR)

After setting the registers in <1> above, check whether the LOCK bit of the LOCKR register is cleared to 0 (PLL is locked), and set the registers as follows.

- (i) System wait control register (VSWC)
   Set to x7H (x: Value set in <1>)
   For example, if 11H is set in <1>, set 17H here.
- (ii) Bus mode control register (BMC)Set the frequency division value of the external bus.
- (iii) System wait control register (VSWC)Re-set the value set in <1>.
- (iv) Clock control register (CKC)Set the internal system clock frequency division value.
- (v) Clock source select register (CKS)
   Switch from OSC output to SSCG output (switch the clock supply to the CPU from the input frequency to the X1 and X2 pins to the frequency multiplied by 8 by the PLL).
- **Remark** The CKC and CKS registers must be rewritten in a special sequence because they are specific registers.

#### <3> Transferring program code to internal instruction RAM

Transfer the program code to the internal instruction RAM by program processing or using the DMA function. When using the DMA function, check the completion of DMA transfer by polling bit 7 (DMAIFn) of the DMA interrupt control register (DMAICn), without using the DMA transfer end interrupt (INTDMAn) (n = 0 to 3). After transferring the program code, set the internal instruction RAM in the read mode using the following procedure.

- Set the read mode by using (clearing to 0) the IRAMM0 bit of the internal instruction RAM mode register (IRAMM). Note that the setting of the IRAMM0 bit must not be changed before it is cleared here.
- (ii) After clearing the IRAMM0 bit of the IRAMM register to 0, read the IRAMM0 bit that has been cleared to 0 to confirm that the read mode has been set (to prevent speculative instruction execution by pipeline operation).
- (iii) Branch to the internal instruction RAM area by executing a branch instruction.
- Cautions 1. After the reset signal has been cleared, the NMI input is masked by hardware. The NMI is unmasked as soon as the IRAMM0 bit of the IRAMM register is cleared in step <3> of the initialization sequence.
  - 2. If it is necessary to confirm NMI input immediately after the reset signal has been cleared and before the internal instruction RAM is set in the read mode, read the NMIRS bit of the NMI reset status register (NRS). If this bit is set to 1, it indicates that the NMI valid edge has been input. Execute the NMI servicing routine as necessary. The NRS register is used only to check NMI input after the reset signal has been cleared and before the internal instruction RAM is set in the read mode. This register is not cleared after the reset signal has been cleared.
  - 3. The software exception and exception trap cannot be masked. Do not execute the TRAP and DBTRAP instructions until the program code has been transferred to the internal instruction RAM.
- Remarks 1. The NMIRS bit of the NRS register is also set to 1 if an NMI is input after the internal instruction RAM has been set in the read mode. In this case, execution automatically branches to the NMI servicing routine and it is not necessary to confirm the status of the NMIRS bit.
  - **2.** The NMI input mask function is valid after the reset signal has been cleared and before the internal instruction RAM is set in the read mode.
  - 3. To write data to instruction RAM bank 0 of the internal instruction RAM in the middle of program execution, set the NP bit of the PSW to 1 to disable NMI and maskable interrupts, so that the software exception and exception trap do not occur. Clear the NP bit after the program has been rewritten, and after it has been confirmed that the IRAMM0 bit of the IRAMM register has been set to 1 and the read mode has been set.
  - 4. NMI and maskable interrupt requests that are generated while the NP bit of the PSW is set to 1 are held pending. An NMI request is acknowledged immediately after the NP bit has been cleared to 0. A maskable interrupt is acknowledged immediately after the NP bit has been cleared to 0 if interrupts are not disabled (DI status) and the interrupt request is not cleared (by clearing the xxIFn bit of the interrupt control register (xxICn) to 0) before the NP bit is cleared to 0, and if the xxMKn bit of the interrupt requests is held pending for each interrupt source, and only one interrupt request is acknowledged even if the same interrupt request is generated two times or more.

# CHAPTER 4 BUS CONTROL FUNCTION

The V850E/ME2 is provided with an external bus interface function by which external I/O and memories, such as ROM and RAM, can be connected.

# 4.1 Features

- 32-bit/16-bit/8-bit data bus sizing function
- 8-space chip select function
- Wait function
  - Programmable wait function, through which up to 7 wait states can be inserted for each memory block
  - External wait function via WAIT pin
- Idle state insertion function
- Bus mastership arbitration function
- Bus hold function
- · External device connection enabled via bus control/port alternate function pins

# 4.2 Bus Control Pins

The following pins are used for connection to external devices.

Bus Control Pin (Function When in Control Mode)	Function When in Port Mode	Register for Port/Control Mode Switching
Data bus (D0 to D15)	-	-
Data bus (D16 to D31)	PDH0 to PDH15 (Port DH)	PMCDH
Address bus (A0, A1)	PAL0, PAL1 (Port AL)	PMCAL
Address bus (A16 to A25)	PAH0 to PAH9 (Port AH)	PMCAH
Chip select (CS0 to CS7, IOWR, IORD)	PCS0 to PCS7 (Port CS)	PMCCS
SDRAM sync control (SDCKE)	PCD0 (Port CD)	PMCCD
Bus clock (BUSCLK)	PCD1 (Port CD)	
SDRAM control (SDCAS, SDRAS)	PCD2, PCD3 (Port CD)	
Read/write control (LLWR/LLBE/LLDQM, LUWR/LUBE/LUDQM, ULWR/ULBE/ULDQM, UUDQM/UUBE/UUWR, RD, WE/WR)	PCT0 to PCT5 (Port CT)	PMCCT
Bus cycle start (BCYST)	PCT7 (Port CT)	
External wait control (WAIT)	PCM0 (Port CM)	PMCCM
Bus hold control (HLDRQ, HLDAK)	PCM2, PCM3 (Port CM)	
SDRAM refresh control (REFRQ)	PCM4 (Port CM)	]
Self-refresh control (SELFREF)	PCM5 (Port CM)	

**Remark** When the system is reset, each bus control pin becomes unconditionally valid. (However, D16 to D31, ULWR/ULBE/ULDQM, and UUWR/UUBE/UUDQM are valid only in 32-bit mode.)

# 4.2.1 Pin status during internal instruction RAM, internal data RAM, and peripheral I/O access

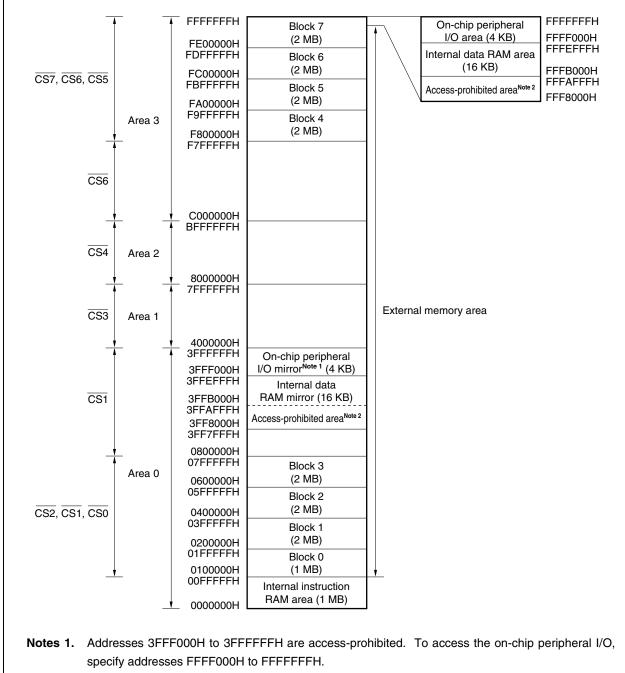

While accessing internal instruction RAM (in the read mode), internal data RAM, and peripheral I/O, the address bus outputs low level, and the data bus outputs nothing and enters the high-impedance state. The external bus control signals become inactive.

When the internal instruction RAM is accessed (in the write mode), the address bus and data bus output data. The external bus control signals other than UUWR, ULWR, LUWR, LUWR, and WR become active. If output of the IOWR signal is enabled by setting the IOEN bit of the bus cycle period control register (BCP) to 1, the IOWR signal becomes active.

# 4.3 Memory Block Function

The 256 MB memory space is divided into four areas including seven 2 MB memory blocks and one 1 MB memory block.

The area that can be used as program area is the 64 MB space of addresses 0000000H to 3FFFFFFH.

2. The operation is not guaranteed if an access-prohibited area is accessed.

#### 4.3.1 Chip select control function

Each memory block can be divided by chip area select control registers 0 and 1 (CSC0, CSC1) to control the chip select signal.

The memory area can be effectively used by dividing it into memory blocks using the chip select control function. The priority order is described below.

# (1) Chip area select control registers 0, 1 (CSC0, CSC1)

These registers can be read or written in 16-bit units and become valid by setting each bit to 1. If different chip select signal outputs are set to the same block, the priority order is controlled as follows.

 $CSC0: \overline{CS0} > \overline{CS2} > \overline{CS1}$  $CSC1: \overline{CS7} > \overline{CS5} > \overline{CS6}$ 

If both the CS0n and CS2n bits of the CSC0 register are set to 0,  $\overline{CS1}$  is output to the corresponding block (n = 0 to 3).

Similarly, if both the CS5n and CS7n bits of the CSC1 register are set to 0,  $\overline{CS6}$  is output to the corresponding block (n = 0 to 3).

Caution Write to the CSC0 and CSC1 registers after reset, and then do not change the set value.

		CS70	CS7 output during block 7 access.
		CS71	CS7 output during block 6 access.
		CS72	CS7 output during block 5 access.
		CS73	CS7 output during block 4 access.

The following diagram shows the  $\overline{CS}$  signal that is enabled for area 0 when the CSC0 register is set to 0F03H.

When the CSC0 register is set to 0F03H,  $\overline{CS0}$  and  $\overline{CS2}$  are output to block 0 and block 1, but since  $\overline{CS0}$  has priority over  $\overline{CS2}$ ,  $\overline{CS0}$  is output if the addresses of block 0 and block 1 are accessed.

If the addresses of block 2 and block 3 are accessed,  $\overline{\text{CS2}}$  is output.

If the addresses of area 0 other than blocks 0 to 3 are accessed,  $\overline{\text{CS1}}$  is output.

The following shows an example when the CSC0 register is set to 0803H and the CSC1 register is set to 0601H.

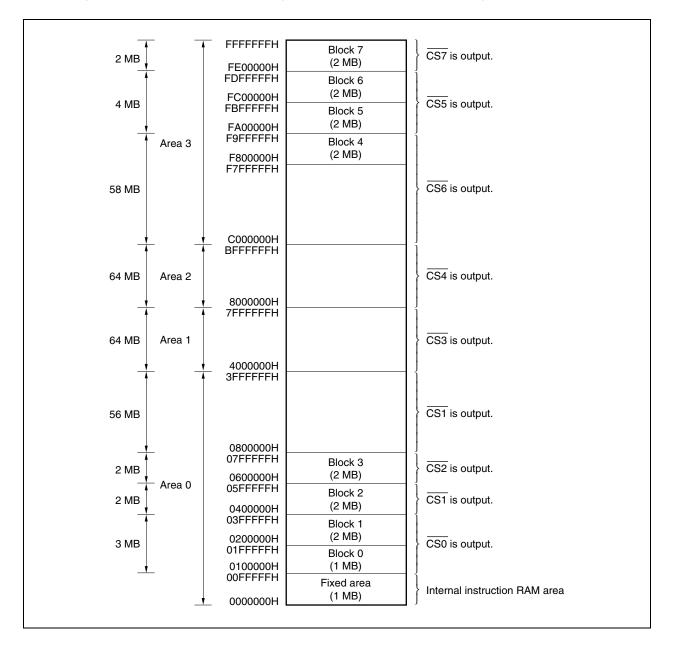

Figure 4-1. Example When CSC0 Register Is Set to 0803H and CSC1 Register Is Set to 0601H

# 4.4 Bus Cycle Type Control Function

In the V850E/ME2, the following external devices can be connected directly to each memory block.

- SRAM, external ROM, external I/O
- Page ROM
- SDRAM

Connected external devices are specified by bus cycle type configuration registers 0 and 1 (BCT0 and BCT1).

# 4.4.1 Bus cycle type configuration registers 0, 1 (BCT0, BCT1)

# (1) Bus cycle type configuration registers 0, 1 (BCT0, BCT1)

These registers can be read or written in 16-bit units.

Be sure to clear bits 14, 10, 6, and 2 to 0. If they are set to 1, the operation is not guaranteed.

Caution Write to the BCT0 and BCT1 registers after reset, and then do not change the set value. Also, do not access an external memory area other than the one for this initialization routine until the initial setting of the BCT0 and BCT1 registers is complete. However, it is possible to access external memory areas whose initialization settings are complete.

# 4.5 Bus Access

# ★ 4.5.1 Number of access clocks

The number of base clocks necessary for accessing each resource is as follows.

	Bus Cycle Configuration	Instruction Fetch	Operand D	ata Access
Resource (Bus Width)			Read	Write
Internal instruction RAM (32 b	pits)	1	1	2 <sup>Note</sup>
Internal data RAM (32 bits)		_		1

**Note** When the internal instruction RAM is accessed (in the write mode), programmable waits, address setup waits, and idle states can be inserted in the CS0 space.

If none of the above states is set, the instruction RAM is accessed using a ×2 BUSCLK frequency clock.

Remark Unit: Clock/access

## 4.5.2 Bus sizing function

The bus sizing function controls the data bus width for each CS space. The data bus width is specified by using the local bus sizing control register (LBS).

# (1) Local bus sizing control register (LBS)

This register can be read or written in 16-bit units.

- Cautions 1. Write to the LBS register after reset, and then do not change the set value. Also, do not access an external memory area other than the one for this initialization routine until the initial setting of the LBS register is complete. However, it is possible to access external memory areas whose initialization settings are complete.
  - 2. When the data bus width is specified as 8 bits, only the signal shown below becomes active.
    - **LLWR:** When accessing SRAM, external ROM, or external I/O (write cycle)
  - 3. When the data bus width is specified as 16 bits, only the signals shown below become active.

# 4.5.3 Endian control function

The endian control function can be used to set processing of word data in memory using either the big endian method or the little endian method for each CS space selected with the chip select signals ( $\overline{CS0}$  to  $\overline{CS7}$ ). Switching of the endian method is specified using the endian configuration register (BEC).

# Caution In the following areas, the data processing method is fixed to little endian, so the setting of the BEC register is invalid.

- On-chip peripheral I/O area
- Internal instruction RAM area
- Internal data RAM area
- Area same as internal data RAM area of addresses 3FF8000H to 3FFBFFFH
- Program area for external memory

## (1) Endian configuration register (BEC)

This register can be read or written in 16-bit units.

Be sure to clear bits 15, 13, 11, 9, 7, 5, 3, and 1 to 0. If they are set to 1, the operation is not guaranteed.

## Caution Write to the BEC register after reset, and then do not change the set value.

#### 4.5.4 Big endian method usage restrictions in NEC Electronics development tools

#### (1) When using a debugger (ID850)

The big endian method is supported only in the memory window display.

## (2) When using a compiler (CA850)

#### (a) Restrictions in C language

- (i) There are restrictions for variables allocated to/located in the big endian space, as shown below.
  - union cannot be used.
  - bitfield cannot be used.
  - Access with cast (changing access size) cannot be used.
  - · Variables with initial values cannot be used.
- (ii) It is necessary to specify the following optimization inhibit options because optimization may cause a change in the access size.
  - For global optimization part (opt850)... -Wo, -XTb
  - For optimization depending on model part (impr850)... -Wi, +arg\_reg\_opt=OFF, +stld\_trans\_opt=OFF

The specification of the optimization inhibit options shown above is not necessary, however, if the access is not an access with cast or with masking/shifting<sup>Note</sup>.

**Note** This is on the condition that a pattern that may cause the following optimization is not used. However, because it is very difficult for users to check the patterns completely in cases such as when several patterns are mixed (especially for optimization depending on model part), it is recommended that the optimization inhibit options shown above be specified.

## (b) Restrictions in assembly language

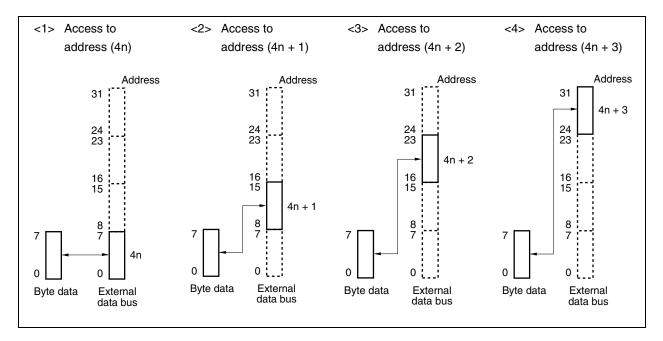

For variables located in the big endian space, a quasi directive that secures an area of other than byte size (.hword, .word, .float, .shword) cannot be used.

## 4.5.5 Bus width

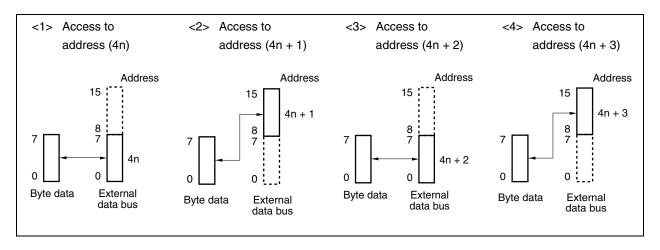

The V850E/ME2 accesses peripheral I/O and external memory in 8-bit, 16-bit, or 32-bit units. The following shows the operation for each type of access. All data is accessed in order starting from the lower order side.

# (1) Byte access (8 bits)

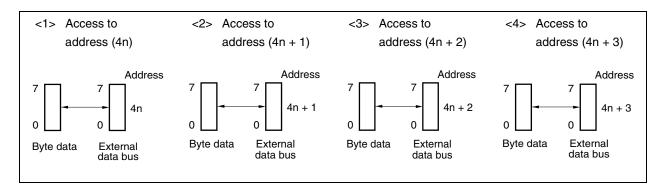

# (a) When the data bus width is 32 bits (little endian)

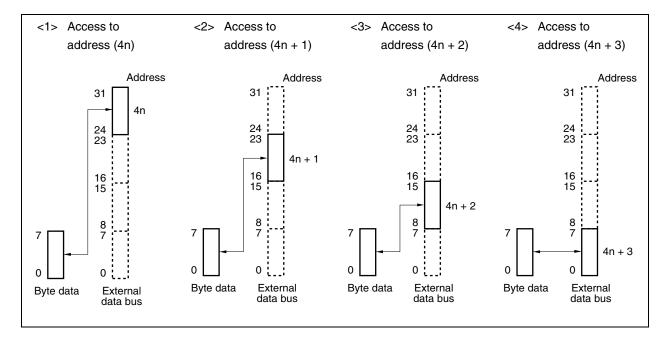

(b) When the data bus width is 16 bits (little endian)

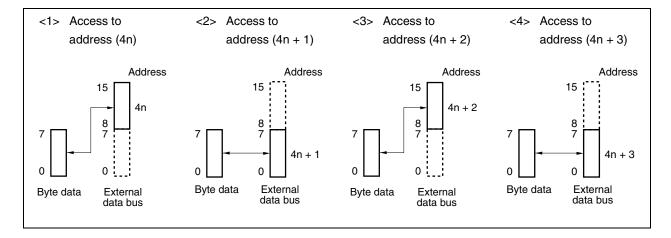

# (c) When the data bus width is 8 bits (little endian)

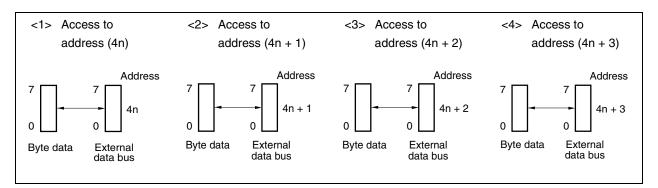

# (d) When the data bus width is 32 bits (big endian)

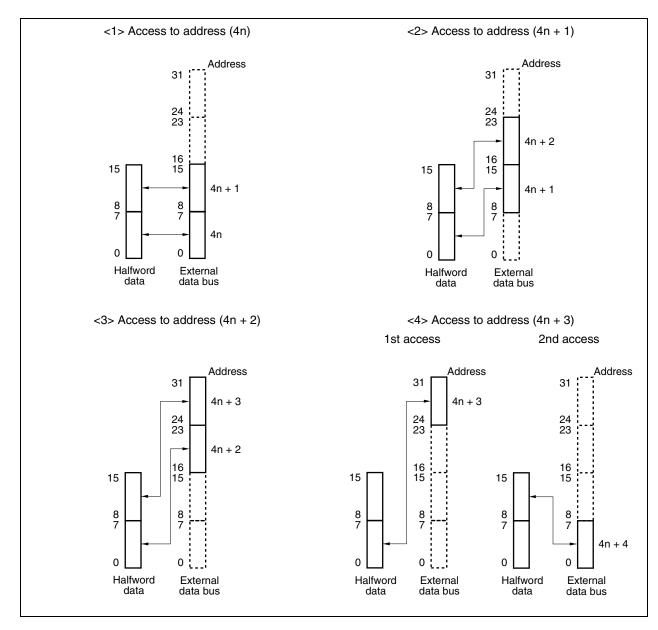

# (e) When the data bus width is 16 bits (big endian)

#### 4.5.6 Data read control function

\*

#### (1) Line buffer control registers 0, 1 (LBC0, LBC1)

The V850E/ME2 has a read buffer.

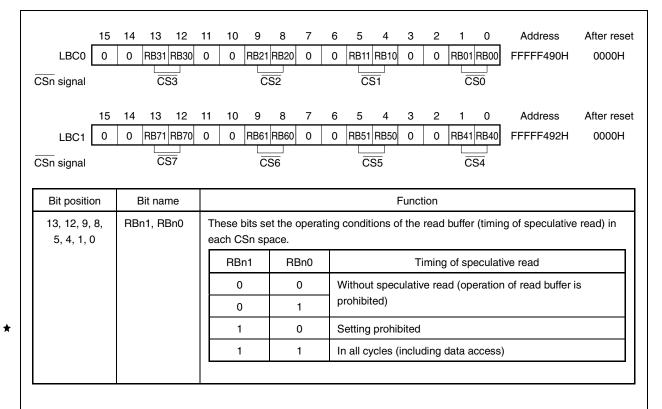

The LBC0 and LBC1 registers set the operating conditions of the read buffer in each CS space.

These registers can be read or written in 16-bit units.

Be sure to clear bits 15, 14, 11, 10, 7, 6, 3, and 2 to 0. If they are set to 1, the operation is not guaranteed.

Cautions 1. Be sure to write data to the LBC0 and LBC1 registers after reset. After writing data to these registers, do not change their values.

2. When the speculative read function is set for each CSn space, do not insert an idle state in the CSn space for which the speculative read function is enabled by the BCC register (n = 0 to 7). If an idle state is required to be inserted in the CSn space for which the speculative read function is enabled, enable the speculative read function for all CSn spaces (set the LBC0 and LBC1 registers to 3333H) or disable the speculative read function for all CSn spaces (set the LBC0 and LBC1 registers to 0000H).

**Remarks 1.** n = 0 to 7

2. If the setting of the RBn1 and RBn0 bits is changed, the data in the read buffer is immediately invalidated.

#### (a) Speculative read function (read buffer function)

The V850E/ME2 has speculative read buffers consisting of 4 words (128 bits). If the operating conditions set by the LBC0 or LBC1 register are satisfied when a read request is issued from the CPU or DMA controller to a CSn space, the requested address is read and the remaining three words of data are read (speculatively) to the read buffers, regardless of whether a request is issued from the CPU or DMA controller. Data is read to the read buffers in the sequence of critical first access.

Example of transfer: For speculative reading of 32 bits

- (i)  $xxxxx00H \rightarrow xxxxx04H \rightarrow xxxxx08H \rightarrow xxxxx0CH$
- (ii)  $xxxxx04H \rightarrow xxxxx08H \rightarrow xxxxx0CH \rightarrow xxxxx00H$
- (iii)  $xxxxx01H \rightarrow xxxxx05H \rightarrow xxxxx09H \rightarrow xxxxx0DH^{Note}$

**Note** If the lower 2 bits of an address are not used in the 32-bit mode, the operation is the same as (i) above.

The four words of data that have been read are held in the read buffers. If the following conditions are satisfied, the data in the buffers is lost.

- Speculative read miss hit (read request to external memory area not stored in read buffer)
- Writing BCT0 or BCT1 register
- Writing LBS register
- Writing LBC0 or LBC1 register
- · Generation of bus hold

\*

- Generation of DMA flyby cycle (not dependent on CS space)
- · Memory write access to speculatively read line address

If the CPU or DMA controller requests reading the data held in the read buffers, the data is transferred to the CPU or DMA controller without generating an external memory cycle.

**Remark** If the speculative read function is enabled in the 32-bit mode (with a 32-bit data bus width) and the LD.W instruction is executed at address xxxxx0DH, the following bus cycles are successively generated.

 $xxxxx0CH \rightarrow xxxxx00H \rightarrow xxxxx04H \rightarrow xxxxx08H \rightarrow$ 

Penalty cycle due to speculative reading

 $xxxxx10H \rightarrow xxxxx14H \rightarrow xxxxx18H \rightarrow xxxxx1CH$ 

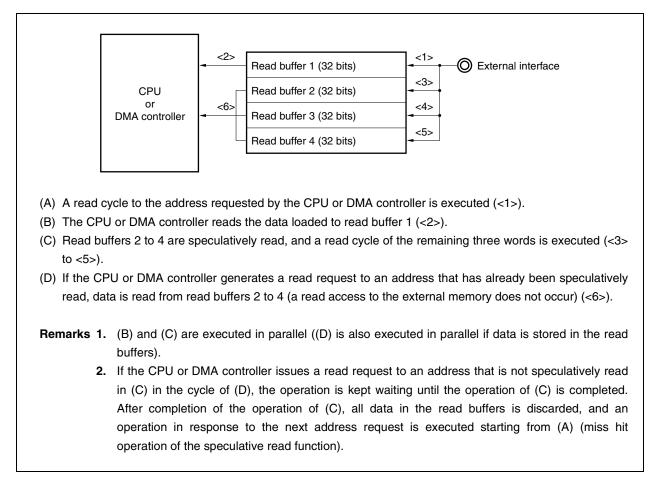

Penalty cycle due to speculative reading

The CPU reads the following data when it stores data in the read buffer.

xxxxx0DH (8 bits)  $\rightarrow$  xxxxx0EH (16 bits)  $\rightarrow$  xxxxx10H (8 bits)

The speculative read operation is outlined below.

#### (b) Write buffer function

The V850E/ME2 has an on-chip write buffer of 4 words (128 bits). The write buffer stores data if a write cycle cannot be executed while the external bus is occupied<sup>Note</sup>. The next instructions are speculatively executed until the write buffer becomes full. The write buffer is valid for all the external memory areas. If a write request is generated while the write buffer is full, the next instruction execution is postponed until there is a vacancy in the write buffer.

While data is being stored in the write buffer (when a write operation to the external memory has not been completed), DMA and bus hold requests are not acknowledged (DMA and bus hold requests are acknowledged and an enable signal is generated after all the data of the write buffers has been written to the external memory).

**Note** The external bus is occupied when there is a bus cycle currently under execution. If instruction fetch cycles are successively executed, all write cycles for the write data stored in the write buffer are always generated after the bus cycle currently under execution (instruction fetch cycle) is completed.

- Cautions 1. Because the write buffer consists of four stages, the write buffer becomes full after 4 bytes (32 bits) when a byte write operation is executed (while a write operation to the external memory is standing by). Similarly, the conditions under which the write buffer becomes full vary due to an address miss-align access, etc.
  - 2. When data is written to an external device, the write operation to the external device may not be executed even when a CPU write operation has been completed by the write buffer. The CPU can access the on-chip peripheral I/O registers after the write operation has been completed, regardless of whether a write operation to the external device is executed. Therefore, if it is necessary to change the value of an on-chip peripheral I/O register after completion of execution of an external memory cycle, write the same value as the default value to the LBC0 or LBC1 register, and then write the on-chip peripheral I/O register other than the LBC0 or LBC1 register without writing an on-chip peripheral I/O register other than the LBC0 or LBC1 register, the register value may be changed before completion of the external memory cycle. Although rewriting the LBC0 and LBC1 registers is prohibited, the same value can be rewritten to the registers in this case. However, if a value different from the default value is written to the LBC0 or LBC1 register, the operation is not guaranteed.
  - 3. During 2-cycle transfer that writes data to the external device, the write operation to the external device may not be completed even if TCn bit of DCHCn register = 1 (DMA transfer completion) is read by the write buffer (n = 0 to 3). If it is necessary to change the value of an on-chip peripheral I/O register after completion of DMA transfer (completion of a write operation to the external device), perform either of the following operations.

\*

- Monitor the TCn signal (the TCn signal becomes active in synchronization with a write operation to the external device).
- After detecting setting (to 1) of the TCn bit, write the same value as the default value to the LBC0 or LBC1 register, and then change the value of the on-chip peripheral I/O register. If the value of an on-chip peripheral I/O register other than the LBC0 and LBC1 registers is changed without writing the same value to LBC0 or LBC1, the value of the on-chip peripheral I/O register may be changed before completion of DMA transfer.

Although rewriting the LBC0 and LBC1 registers is prohibited, the same value can be rewritten to the registers in this case. However, if a value different from the default value is written to the LBC0 or LBC1 register, the operation is not guaranteed.

#### 4.6 Bus Clock Control Function

#### (1) Bus mode control register (BMC)

This register sets the division rate of the bus clock (BUSCLK) with respect to the internal system clock. Writing the BMC register stops BUSCLK once at low level. BUSCLK resumes operation with the set divided clock after it has been stopped. While BUSCLK is stopped, the operation of the SDRAM refresh control register (RFSn) of SDRAM is also stopped (n = 1, 3, 4, 6).

This register can be read or written in 8-bit units.

Be sure to clear bits 7 to 2 to 0. If they are set to 1, the operation is not guaranteed.

# Cautions 1. Write the BMC register after reset, and then do not change the value that has been written.

2. Before writing to the BMC register, be sure to set the VSWC register to x7H (x: Value before setting the BMC register). After writing the set value to the BMC register, re-set the value of the VSWC register to the value before the set value of the BMC register was written (see 3.4.10 Initialization sequence).

#### 4.7 Wait Function

#### 4.7.1 Programmable wait function

#### (1) Data wait control registers 0, 1 (DWC0, DWC1)

To facilitate interfacing with low-speed memory and I/Os, it is possible to insert up to 7 data wait states in the starting bus cycle for each CS space.

The number of wait states can be specified by program using DWC0 and DWC1 registers. Just after system reset, all blocks have 7 data wait states inserted.

These registers can be read or written in 16-bit units.

- Cautions 1. The internal instruction RAM area (in the read mode) and internal data RAM area are not subject to programmable waits and ordinarily no wait access is carried out. When the internal instruction RAM area is accessed (in the write mode), the programmable wait value set for the CS0 space becomes valid. The on-chip peripheral I/O area is not subject to programmable waits, with wait control performed by each peripheral function only.
  - 2. In the following cases, the settings of the DWC0 and DWC1 registers are invalid (wait control is performed by each memory controller).
    - Page ROM on-page access
    - SDRAM access
  - 3. Write to the DWC0 and DWC1 registers after reset, and then do not change the set values. Also, do not access an external memory area other than the one for this initialization routine until the initial setting of the DWC0 and DWC1 registers is complete. However, it is possible to access external memory areas whose initialization settings are complete.

#### (2) Address setup wait control register (ASC)

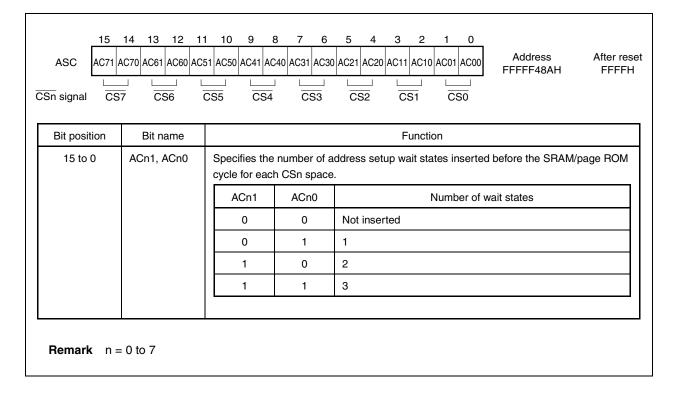

The V850E/ME2 allows insertion of address setup wait states before the SRAM/page ROM cycle (the setting of the ASC register in the SDRAM cycle is invalid).

The number of address setup wait states can be set with the ASC register for each CS space.

This register can be read or written in 16-bit units.

Cautions 1. The internal instruction RAM area (in the read mode), internal data RAM area, and onchip peripheral I/O area are not subject to address setup wait insertion. When the internal instruction RAM area is accessed (in the write mode), the address setup wait value set for the CS0 space becomes valid.

- 2. During an address setup wait, the  $\overline{WAIT}$  pin-based external wait function is disabled.
- 3. Write to the ASC register after reset, and then do not change the set value.

#### (3) Bus cycle period control register (BCP)

\*

With the V850E/ME2, the operations of IORD and IOWR can be enabled or disabled in the SRAM, external ROM, and external I/O cycles.

This register can be read or written in 8-bit or 1-bit units.

Be sure to clear bits 7 to 4 and 2 to 0 to 0. If they are set to 1, the operation is not guaranteed.

Cautions 1. During a flyby DMA transfer for SRAM, external ROM, or external I/O, the IORD and IOWR signals are always output, irrespective of the IOEN bit setting.

Flyby transfer from external I/O to external memory:  $\overline{IORD}$  and  $\overline{WR}$  signals become active. Flyby transfer from external memory to external I/O:  $\overline{IOWR}$  and  $\overline{RD}$  signals become active.

In page ROM cycle, on the other hand, the IOEN bit setting has no meaning.

- 2. Write to the BCP register after reset, and then do not change the set values.
- 3. If the internal instruction RAM is accessed while the IOEN bit is set (1) (write mode), the IOWR signal becomes active.

				1	Enables the external I/O	•	of IORD a	nd IOWR in	n SRAM, externa	I ROM, and

#### (4) DMA flyby transfer wait control register (FWC)

The FWC register sets the number of data wait cycles during DMA flyby transfer for each channel n (see the timing chart in **6.5.2 Flyby transfer**) (n = 0 to 3).

The set value of this register is valid during DMA flyby transfer, and the set values of the DWC0, DWC1, and PRC registers are invalid.

This register can be read or written in 16-bit units.

- Cautions 1. The internal instruction RAM area and internal data RAM area are not subject to the programmable wait operation and are always accessed with no wait cycle. The on-chip peripheral I/O area is also not subject to the programmable wait operation, and is subject only to wait control by each peripheral function.
  - 2. Write to the FWC register after reset, and then do not change the set values.
  - 3. DMA flyby transfer that accesses SDRAM inserts the set value + 1 data wait cycles.

#### 4.7.2 External wait function

When an extremely slow device, I/O, or asynchronous system is connected, an arbitrary number of wait states can be inserted in the bus cycle by the external wait pin (WAIT) for synchronization with the external device.

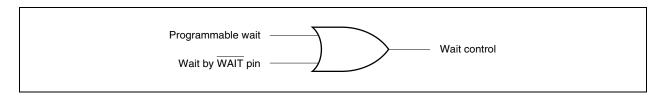

Just as with programmable waits, accessing internal instruction RAM (in the read mode), internal data RAM, and on-chip peripheral I/O areas cannot be controlled by external waits.

The external WAIT signal can be input asynchronously to BUSCLK and is sampled at the rising edge of the clock in the T1 and TW states of a bus cycle. If the setup/hold time in the sampling timing is not satisfied, the wait state may or may not be inserted in the next state.

## Caution Be sure to make the WAIT pin high when the internal instruction RAM is accessed (in the write mode).

#### 4.7.3 Relationship between programmable wait and external wait

A wait cycle is inserted as the result of an OR operation between the wait cycle specified by the set value of the programmable wait and the wait cycle controlled by the  $\overline{WAIT}$  pin. In other words, the number of wait cycles is determined by the side with the greatest number of cycles.

For example, if the timings of the programmable wait and the WAIT pin signal are as illustrated below, three wait states will be inserted in the bus cycle.

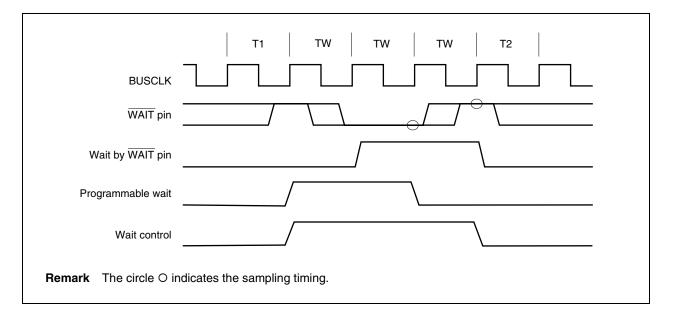

Figure 4-6. Example of Wait Insertion

### 4.7.4 Bus cycles in which wait function is valid

In the V850E/ME2, the number of waits can be specified according to the memory type specified for each memory block. The following shows the bus cycles in which the wait function is valid and the registers used for wait setting.

	Bus Cycle		Type of Wait	Program	mable Wait Setting

#### 4.8 Idle State Insertion Function

#### (1) Bus cycle control register (BCC)

To facilitate interfacing with low-speed memory devices, an idle state (TI) can be inserted into the current bus cycle after the T2 state to meet the data output float delay time (tDF) on memory read access for each CS space. The bus cycle following the T2 state starts after the idle state is inserted.

An idle state is inserted at the timing shown below.

- After read/write cycles for SRAM, external I/O, or external ROM
- After a read cycle for page ROM
- After a read cycle for SDRAM

The idle state insertion setting can be specified by program using the bus cycle control register (BCC). Immediately after the system reset, idle state insertion is automatically programmed for all memory blocks. For the timing when an idle state is inserted, see the memory access timings in Chapter 5. This register can be read or written in 16-bit units.

Cautions 1. The internal instruction RAM area (in the read mode), internal data RAM area, and onchip peripheral I/O area are not subject to idle state insertion. When the internal instruction RAM area is accessed (in the write mode), the idle state value set for the CS0 space becomes valid.

- 2. Write to the BCC register after reset, and then do not change the set values. Also, do not access an external memory area other than the one for this initialization routine until the initial setting of the BCC register is complete. However, it is possible to access external memory areas whose initialization settings are complete.
- 3. The chip select signal ( $\overline{CSn}$ ) does not become active in the idle state (n = 0 to 7).

#### (2) DMA flyby transfer idle control register (FIC)

The FIC register sets the number of idle states during DMA flyby transfer for each DMA channel n (see the timing chart in **6.5.2 Flyby transfer**) (n = 0 to 3). The idle state is inserted at the end of DMA flyby transfer. During DMA flyby transfer, the set value of this register is valid, and the set value of the bus cycle control register (BCC) is invalid.

This register can be read or written in 16-bit units.

# Cautions 1. The internal instruction RAM area, internal data RAM area, and on-chip peripheral I/O area are not subject to idle state insertion.

2. Write to the FIC register after reset, and then do not change the set values.

#### 4.9 Instruction Cache Function

The V850E/ME2 has an 8 KB 2-way set associative instruction cache.

This instruction cache uses an LRU (Least Recently Used) algorithm. This cache uses two ways as the cache, with the way to be replaced in case of a miss hit determined by the internal LRU bit. If the way is specified as a cacheable area, a 4-word burst sequential read cycle is issued (when the external 32-bit bus operates) (when the external 16-bit bus operates, an 8-halfword burst read cycle is issued).

Set the instruction cache using the following procedure, after system reset.

- <1> Wait until the value of the ICC register reaches "0000H" (until the tag is initialized).
- <2> Make the setting of the instruction cache cacheable by using the BHC register.

## Caution Be sure to set the BHC register in an uncached area (instructions cannot be fetched correctly if it is set from a cacheable area).

#### 4.9.1 Cache configuration register (BHC)

٠

#### (1) Cache configuration register (BHC)

This register can set the configuration of the cache memory in each CS space selected by the chip select signals (CS0 to CS2). Setting a cacheable area becomes valid immediately after the BHC register has been set.

This register can be read or written in 16-bit units.

Be sure to clear bits 15 to 5 to 0. If they are set to 1, the operation is not guaranteed.

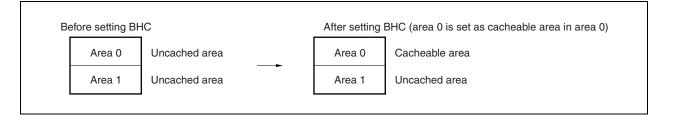

#### Cautions 1. Write the BHC register after reset, and then do not change the set values.

2. The area that includes the instruction that sets the BHC register cannot be set from an uncached area to a cacheable area, or from a cacheable area to an uncached area. In this case, branch to area 1 and then set area 0 to a cacheable area by an instruction in area 1. If necessary, branch to area 0 again.

An uncached area and a cacheable area can be set in any CS space in the internal instruction RAM area.

#### (Example of prohibited setting)

• If the instruction that sets the BHC register is in area 0

Cautions 3. If adjacent memory areas are a cacheable area and an uncached area, only a branch instruction can be used to successively access this memory boundary. The operation is not guaranteed if this memory boundary is successively accessed by an instruction other than a branch instruction.

#### (Operation example)

- An access from area 0 to area 1 can be made only by a branch instruction.
- Successive accesses can be made from area 1 to area 2.

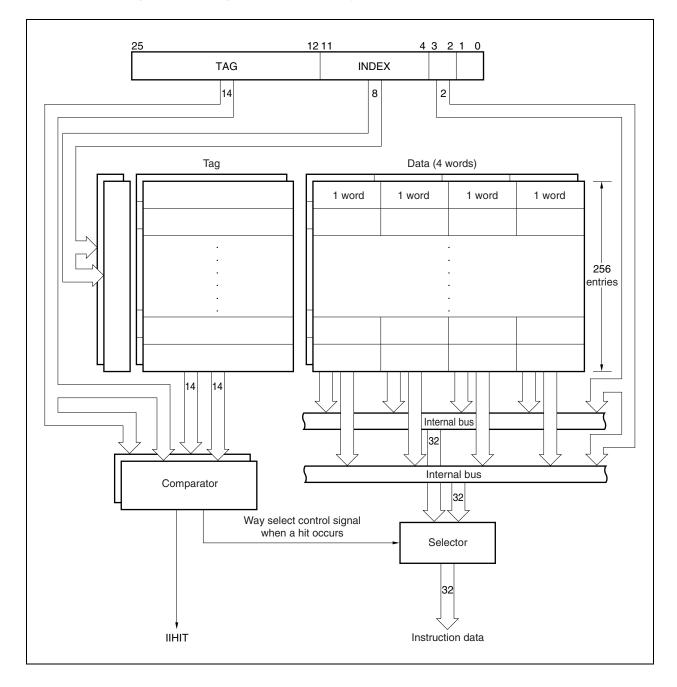

Area 0	Uncached area
Area 1	Cacheable area
Area 2	Cacheable area

#### 4.9.2 8 KB 2-way set associative cache

The data memory of the 8 KB 2-way set associative cache has two ways each consisting of 4-word lines and blocks of 256 entries, and has a total capacity of 8 KB. If a cache miss occurs, the data memory is refilled in 1-line units.

Only the instructions related to data access of the cacheable area can be cached in the instruction cache.

#### 4.9.3 LRU algorithm

This algorithm is used to record accesses to blocks and replace the block that has not been used for the longest time, so that information that may be necessary is not discarded immediately.

## 4.9.4 Instruction cache control function

#### (1) Instruction cache control register (ICC)

This register sets two types of functions, tag clear and auto fill.

This register can be read or written in 16-bit units.

If the higher 8 bits of the ICC register are used as an ICCH register, and the lower 8 bits, as an ICCL register,

these registers can be read or written in 8-bit or 1-bit units.

Bit 12 can only be read and cleared.

Be sure to clear bits 15 to 13, 11 to 5, 3, and 2 to 0. If they are set to 1, the operation is not guaranteed.

## Cautions 1. Do not forcibly clear bits 0, 1, and 4 when they are set to 1.

- 2. Do not set bit 4 to 1 at the same time as the other bits.
- 3. Do not set bit 12 to 1. This bit can only be cleared to 0.
- 4. Be sure to set the ICC register in an uncached area (except setting of bit 4).

#### (2) Instruction cache data configuration register (ICD)

This register sets the address of the memory area that is automatically filled by the auto fill function. This register can be read or written in 16-bit units.

Be sure to clear bit 0 to 0. If it is set to 1, the operation is not guaranteed.

- Cautions 1. Do not rewrite the ICD register during the auto fill operation. The operation is not guaranteed if it is rewritten.
  - 2. Because the default value of the ICD register is undefined, be sure to set a value to the ICD register when the auto fill function is used, and then set the FILL0 bit of the ICC register to 1. If the FILL0 bit of the ICC register is set to 1 without setting a value to the ICD register, the operation is not guaranteed.

#### 4.9.5 Tag clear function

The tag of one way is cleared (invalidated).

After reset, all the ways, tags, and LRU are automatically cleared (invalidated).

The instruction cache tag is cleared using the following procedure.

- <1> The ICC register is read to confirm that both the TCLR0 and TCLR1 bits are cleared to 0.
- <2> The ICC register is read to confirm that the LOCKI0 bit is cleared to 0. Bit 13 of the ICC register is always cleared to 0.
- <3> The TCLR0 and TCLR1 bits of the ICC register are set as follows.
- Cautions 1. Perform operations <1> to <3> above (tag clear) in an uncached area (the tag is not cleared from a cacheable area).
  - To clear both ways 0 and 1 at the same time
    - (a) Set the TCLR0 and TCLR1 bits to 1.
    - (b) Read the TCLR0 and TCLR1 bits to confirm that they are cleared to 0.
  - To clear ways 0 and 1 separately<sup>Note</sup>
    - (a) Set the TCLR0 bit to 1.
    - (b) Read the TCLR0 bit to confirm that it is cleared to 0.
    - (c) Set the TCLR1 bit to 1.
    - (d) Read the TCLR1 bit to confirm that it is cleared to 0.

Note The ways can be cleared separately also in the order of (c) - (d) - (a) - (b).

2. The counter for clearing the tag of ways 0 and 1 is shared.

Therefore, clear the tag (by setting the TCLR0 or TCLR1 bit of the ICC register) when the counter for clearing the tag is stopped (when TCLR0 = TCLR1 = 0). When clearing the tags of ways 0 and 1 separately, the counter stops while a tag is being cleared if the tag of one other way is cleared while the tag of the other way is being cleared (TCLR0 or TCLR1 = 1). Consequently, the tag cannot be cleared correctly because the tag of the other way is cleared with the counter indicating a midway value. Be sure to clear the tag of one other way after confirming that the tag of the other way has been cleared (TCLR0 or TCLR1 = 0).

There is no problem if both the bits are set at the same time as follows.

3. Do not perform other processing in parallel with clearing the tag until it is confirmed by reading the TCLR0 and TCLR1 bits of the ICC register that the tag has been cleared to 0.

#### 4.9.6 Auto fill function (way 0 only)

The instruction of one way is automatically filled.

The way that has been filled automatically is automatically locked and prohibited from being written, and performs the same operation as ROM that can be accessed in one cycle. After the way is unlocked, it operates as an instruction cache again.

The instruction cache is automatically filled using the following procedure.

- <1> Clear (invalidate) the tag of way 0 (see 4.9.5 Tag clear function).
- <2> Set information on the tag corresponding to the memory area to be automatically filled to the ICD register.
- <3> Branch to the cacheable area corresponding to the tag information set to the ICD register.
- <4> Set the FILL0 bit of the ICC register to 1.
- <5> When auto fill is completed, the LOCKI0 bit of the ICC register is automatically set to 1, and way 0 is locked. At this time, read the FILL0 bit of the ICC register at the same time to confirm that this bit is cleared to 0.

#### Caution Perform the above operations in the following areas.

<1>, <2>, <3>...... Uncached area

<4> ..... Cacheable area

If the FILL0 bit of the ICC register is set to 1 from an uncached area, auto fill cannot be executed (is invalidated).

<5>..... This can be done from both an uncached area and a cacheable area.

Remark To unlock the way, clear the LOCKI0 bit of the ICC register to 0.

#### 4.10 Internal Instruction RAM Control Function

The V850E/ME2 has 128 KB of instruction RAM (16 KB  $\times$  32 bits  $\times$  2 banks). While one bank is being read, the other bank can be written in parallel.

#### 4.10.1 Internal instruction RAM mode register (IRAMM)

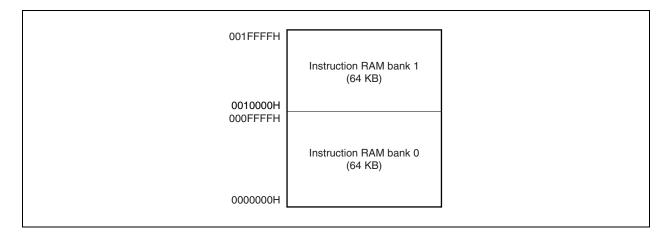

#### (1) Internal instruction RAM mode register (IRAMM)

This register specifies a mode in which the instruction RAM is accessed. This register can be read or written in 8-bit or 1-bit units.

- Cautions 1. When the setting of a mode is changed, the next access (such as code fetching) to the internal instruction RAM may be executed first because of the pipeline operation of the CPU. When the setting of the IRAMM register is changed, therefore, be sure to read the IRAMM register to confirm that writing has been executed, and then execute an access to the internal instruction RAM.
  - 2. Data can be written to the internal instruction RAM only by a word access.
  - 3. Address miss-align access to the internal instruction RAM is prohibited.

Figure 4-8. Memory Map of Internal Instruction RAM

#### 4.10.2 Operation

## (1) Read operation

The internal instruction RAM can be read by normal RAM access without having to be aware of the banks if the read mode is selected by the IRAMM register.

#### Cautions 1. A bank in the write mode cannot be read.

2. The internal instruction RAM (in the read mode) is accessed using the x1 internal system clock.

#### (2) Write operation

The internal instruction RAM can be written by normal RAM access without having to be aware of the banks if the write mode is selected by the IRAMM register.

#### Cautions 1. A bank in the read mode cannot be written.

2. Internal instruction RAM bank 0 area is allocated to interrupt and exception tables. Disable interrupts until writing an instruction code to bank 0 of the internal instruction RAM is completed. Similarly, disable interrupts when bank 0 of the internal instruction RAM is set in the write mode.

For disabling maskable interrupts, refer to interrupt mask registers 0 to 5 (IMR0 to IMR5) (7.3.5 Interrupt mask registers 0 to 5 (IMR0 to IMR5)). To disable the non-maskable interrupt, set the NP bit of the PSW to 1 to disable multiple interrupts (see 3.2.2 (2) Program status word (PSW)). For the NMI mask operation when reset is cleared, refer to the NMI reset status register (NRS) (7.3.6 NMI reset status register (NRS)).

3. When the internal instruction RAM is accessed (in the write mode), programmable waits, address setup waits, and idle states can be inserted in the CS0 space. If none of the above states is set, the instruction RAM is accessed using a ×2 BUSCLK frequency clock.

#### 4.10.3 Cautions

- (1) Disable all interrupts from when reset is cleared until when program codes are completely transferred to the internal instruction RAM. It is not necessary to disable maskable interrupts because they are masked by default. Because the software exception and exception trap cannot be masked, do not execute the TRAP and DBTRAP instructions until transfer of program codes to the internal instruction RAM is completed.
- (2) After reset has been cleared, the NMI input is masked by hardware. The NMI is unmasked as soon as the IRAMM0 bit of the IRAMM register has been cleared to 0.
- (3) To write data to instruction RAM bank 0 of the internal instruction RAM, set the NP bit of the PSW to 1 to disable the NMI and maskable interrupts and suppress occurrence of the software exception and exception trap. Clear the NP bit by setting the IRAMM0 bit of the IRAMM register to 1 and confirming that the read mode is set, after the program has been rewritten.
- (4) NMI or maskable interrupt requests that have been generated while the NP bit of the PSW is set to 1 are held pending. An NMI request is acknowledged immediately after the NP bit has been cleared to 0. A maskable interrupt is acknowledged immediately after the NP bit has been cleared to 0, if the interrupt request is not cleared (by clearing the xxIFn bit of the interrupt control register (xxICn) to 0), if interrupts are not disabled (DI status), and if the xxMKn bit of the interrupt control register is not set to 1 before the NP bit is cleared to 0. However, only one interrupt request, NMI request or a maskable interrupt request, can be held pending per interrupt source. Even if the same interrupt request is generated more than once, only the first interrupt request is acknowledged (xx: Peripheral unit identification name (see Table 7-2), n: Peripheral unit number (see Table 7-2)).
- ★ (5) When the internal instruction RAM is accessed (in the write mode), the address bus and data bus output data. The external bus control signals other than UUWR, ULWR, LUWR, LUWR, and WR become active. If output of the IOWR signal is enabled by setting the IOEN bit of the bus cycle period control register (BCP) to 1, the IOWR signal becomes active.

#### 4.11 Bus Hold Function

#### 4.11.1 Function outline

If the PCM2 and PCM3 pins are specified in the control mode, the HLDAK and HLDRQ functions become valid.

If it is determined that the HLDRQ pin has become active (low level) as a bus mastership request from another bus master, the external address/data bus and each strobe pin are shifted to high impedance and then released (bus hold state). If the HLDRQ pin becomes inactive (high level) and the bus mastership request is canceled, driving of these pins begins again.

During the bus hold period, the internal operations of the V850E/ME2 continue until the external memory or a peripheral I/O register is accessed.

The bus hold state can be known by the  $\overline{HLDAK}$  pin becoming active (low level). The period from when the  $\overline{HLDRQ}$  pin becomes active (low level) to when the  $\overline{HLDAK}$  pin becomes active (low level) is at least 2 clocks.

In a multiprocessor configuration, etc., a system with multiple bus masters can be configured.

State	Data Bus Width	Access Type	Timing at Which Bus Hold Request Cannot Be Acknowledged		
CPU bus lock	32 bits	Word access for 4n+1 address	Between first and second accesses		
			Between second and third accesses		
		Word access for 4n+2 address	Between first and second accesses		
		Word access for 4n+3 address	Between first and second accesses		
			Between second and third accesses		
		Halfword access for odd address	Between first and second accesses		
	16 bits	Word access for even address	Between first and second accesses		
		Word access for odd address	Between first and second accesses		
			Between second and third accesses		
		Halfword access for odd address	Between first and second accesses		
	8 bits	Word access	Between first and second accesses		
			Between second and third accesses		
			Between third and forth accesses		
		Halfword access	Between first and second accesses		
Read modify write access of bit manipulation instruction	_	-	Between read access and write access		

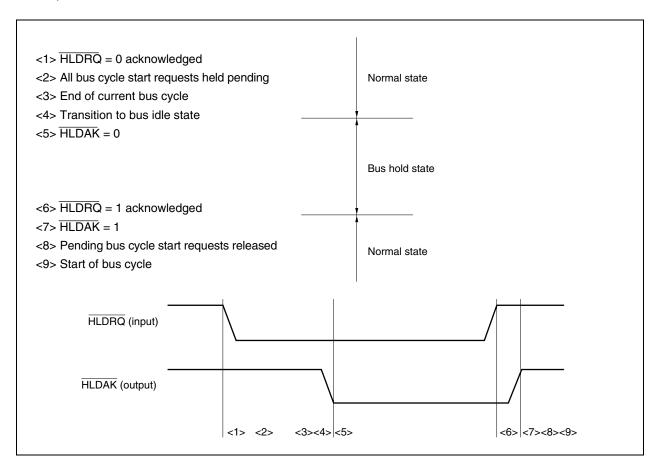

Cautions 1. When an external bus master accesses SDRAM during a bus hold state, make sure that the external bus master executes the all-bank precharge command.

The CPU always executes the all-bank precharge command to release a bus hold state. In a bus hold state, do not allow an external bus master to change the SDRAM command register value.

 The HLDRQ function is invalid during a reset period. The HLDAK pin becomes active either immediately after or after the insertion of a 1-clock address cycle from when the RESET pin is set to inactive following the simultaneous activation of the RESET and HLDRQ pins. When a bus master other than the V850E/ME2 is externally connected, use the RESET signal for bus arbitration at power-on.

#### 4.11.2 Bus hold procedure

The procedure of the bus hold function is illustrated below.

#### 4.11.3 Operation in power-save mode

In the software STOP or IDLE mode, the internal system clock is stopped. Consequently, the bus hold state is not set since the HLDRQ pin cannot be acknowledged even if it becomes active.

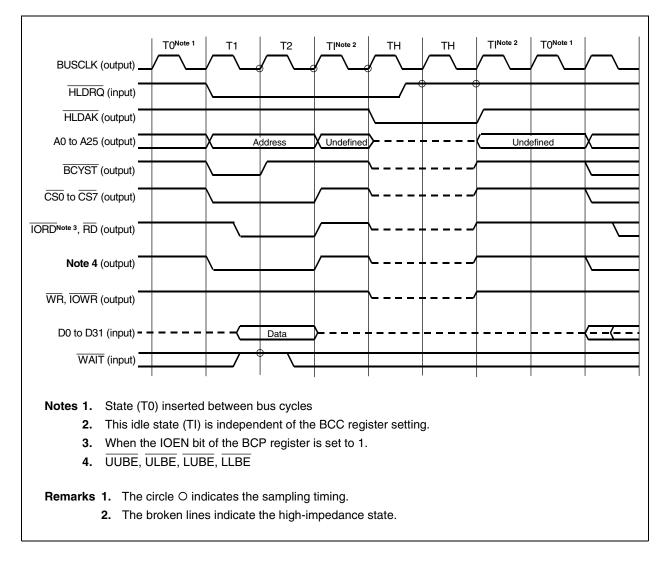

In the HALT mode, the  $\overline{\text{HLDAK}}$  pin immediately becomes active when the  $\overline{\text{HLDRQ}}$  pin becomes active, and the bus hold state is set. When the  $\overline{\text{HLDRQ}}$  pin becomes inactive after that, the  $\overline{\text{HLDAK}}$  pin also becomes inactive. As a result, the bus hold state is cleared and the HALT mode is set again.

#### (4) SDRAM (when written, when bus hold request acknowledged during on-page access)

## 4.12 Bus Priority Order

There are five external bus cycles: bus hold, instruction fetch, operand data access, DMA cycle, and refresh cycle.

In order of priority, bus hold is the highest, followed by the refresh cycle, DMA cycle, operand data access, and instruction fetch, in that order.

An instruction fetch may be inserted between a read access and write access during a read modify write access. Also, an instruction fetch may be inserted between bus accesses when the CPU bus clock is used.

Priority Order	External Bus Cycle	Bus Master
High	Bus hold	External device
	Refresh cycle	SDRAM controller
	DMA cycle	DMA controller
	Operand data access	CPU
Low	Instruction fetch	CPU

Table 4-2. Bus Priority Order

### 4.13 Boundary Operation Conditions

### 4.13.1 Program space

Branching to the on-chip peripheral I/O area is prohibited. If the above is performed, undefined data is fetched, and fetching from the external memory is not performed.

## 4.13.2 Data space

The V850E/ME2 is provided with an address misalign function.

Through this function, regardless of the data format (word or halfword), data can be allocated to all addresses. However, in the case of word data and halfword data, if the data is not subject to boundary alignment, the bus cycle will be generated at least 2 times and bus efficiency will drop.

### (1) External bus width: 16 bits

#### (a) In the case of halfword-length data access

When the address's LSB is 1, a byte-length bus cycle will be generated 2 times.

### (b) In the case of word-length data access

- (i) When the address's LSB is 1, bus cycles will be generated in the order of byte-length bus cycle, halfword-length bus cycle, and byte-length bus cycle.
- (ii) When the address's lower 2 bits are 10, a halfword-length bus cycle will be generated 2 times.

### (2) External bus width: 32 bits

### (a) In the case of halfword-length data access

When the address's lower 2 bits are 11, a byte-length bus cycle will be generated 2 times.

#### (b) In the case of word-length data access

When the address's lower 2 bits are 10, a halfword-length bus cycle will be generated 2 times.

### \* 4.14 Timing at Which T0 State Is Not Inserted

A T0 state is not inserted at the following timing.

#### (1) Read

- O During a refill operation when instruction cache is used (in the second and subsequent cycles)
- O During speculative reading (in the second and subsequent cycles)
- O If a read request (including a read request by instruction fetch or DMA) is generated before a write operation to the external device is completed when a read operation occurs immediately after a write operation
- If a read request (including a read request by instruction fetch or DMA) that is greater than the bus width of the external device is generated (in the second and subsequent cycles)

### [Example]

- · 32-bit read access with 16-bit external bus width
- 32-bit or 16-bit read access with 8-bit external bus width

## (2) Write

- O If a write request (including a write request by DMA) is generated before a write operation to the external device is completed when a write operation occurs immediately after a write operation, and data is stored in the write buffer (a cycle in which the data stored in the write buffer is written to the external device)
- If a write request (including a write request by DMA) is generated during a speculative read operation (if data is stored in the write buffer)
- O If a write request (including a write request by DMA) greater than the bus width of the external bus is generated (after the second and subsequent cycles)

### [Example]

- · 32-bit write access with external 16-bit bus width
- · 32-bit or 16-bit write access with external 8-bit bus

# CHAPTER 5 MEMORY ACCESS CONTROL FUNCTION

# 5.1 SRAM, External ROM, External I/O Interface

## 5.1.1 Features

- SRAM is accessed in a minimum of 2 states.
- Up to 7 states of programmable data waits can be inserted by setting the DWC0 and DWC1 registers (DMA flyby transfer: FWC register).
- Data wait can be controlled via WAIT pin input.
- Up to 3 idle states can be inserted after a read/write cycle by setting the BCC register (DMA flyby transfer: FIC register).
- Up to 3 address setup wait states can be inserted by setting the ASC register.
- DMA flyby transfer can be activated (SRAM  $\rightarrow$  external I/O, external I/O  $\rightarrow$  SRAM)

# 5.2 Page ROM Controller (ROMC)

The page ROM controller (ROMC) is provided for accessing ROM (page ROM) with a page access function.

Addresses are compared with the immediately preceding bus cycle and wait control for normal access (off-page) and page access (on-page) is executed. This controller can handle page widths from 8 to 128 bytes.

# 5.2.1 Features

- Direct connection to 8-bit/16-bit/32-bit page ROM supported
- For 32-bit bus width: 2/4/8/16/32-word page access supported For 16-bit bus width: 4/8/16/32/64-word page access supported For 8-bit bus width: 8/16/32/64/128-word page access supported
- Page ROM is accessed in a minimum of 2 states.
- On-page judgment function
- Addresses to be compared can be changed by setting the PRC register.
- Up to 7 states of programmable data waits can be inserted by setting the following registers.
  - During on-page cycle: PRC register
  - During off-page cycle: DWC0 and DWC1 registers
  - During DMA flyby cycle: FWC register
- Waits can be controlled via WAIT pin input.
- DMA flyby cycle can be activated (page ROM  $\rightarrow$  external I/O)
- SRAM write cycle is started when a write cycle request is issued to a CSn space (n = 0 to 7) where page ROM is located

# 5.2.2 Page ROM connection

Examples of connection to page ROM are shown below.

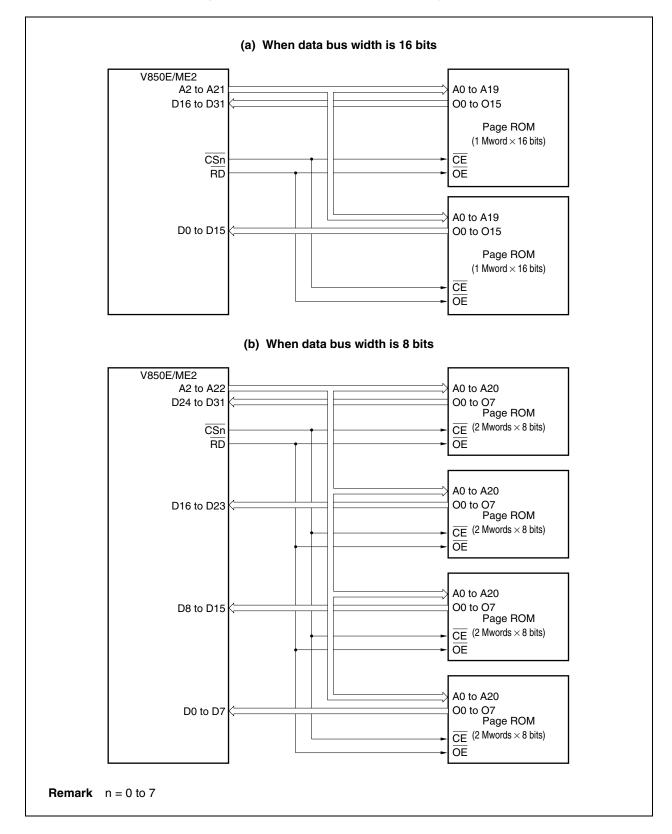

Figure 5-3. Examples of Connection to Page ROM

## 5.2.3 On-page/off-page judgment

Whether a page ROM cycle is on-page or off-page is judged by latching the address of the previous cycle and comparing it with the address of the current cycle. If no speculative reading is specified (RBn1 and RBn0 bits of the LBCm register = 00, 01), an off-page cycle is always started (m = 0, 1, n = 0 to 7).

One of the addresses (A3 to A6) is set as the masking address (no comparison is made) according to the configuration of the connected page ROM and the number of continuously readable bits set by the page ROM configuration register (PRC).

An example of controlling address masking when four page ROMs of 1 Mword  $\times$  8 bits are connected is shown below.

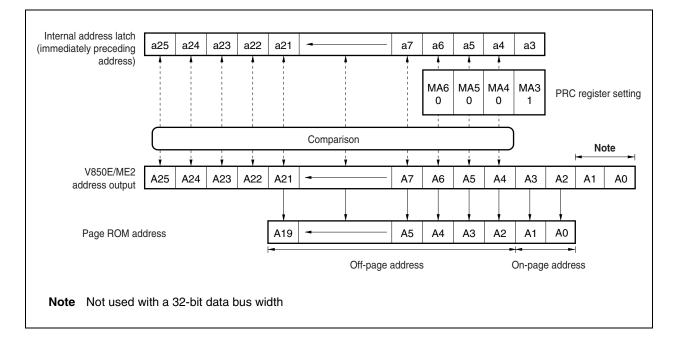

Figure 5-4. Example of Control by MA6 to MA3 Bits of PRC Register

### 5.2.4 Page ROM configuration register (PRC)

This register specifies whether page ROM cycle on-page access is enabled or disabled. If on-page access is enabled, the masking address (no comparison is made) out of the addresses (A3 to A6) corresponding to the configuration of the connected page ROM and the number of bits that can be read continuously, as well as the number of waits corresponding to the internal system clock, are set.

This register can be read or written in 16-bit units.

Caution Write to the PRC register after reset, and then do not change the set value. Also, do not access an external memory area other than the one for this initialization routine until the initial setting of the PRC register is complete. However, it is possible to access external memory areas whose initialization settings are complete.

# 5.3 DRAM Controller (SDRAM)

## 5.3.1 Features

- Burst length: 1
- Wrap type: Sequential
- CAS latency: 1, 2, and 3 supported (only 2 and 3 supported during DMA flyby transfer)
- 4 types of SDRAM can be assigned to 4 memory blocks.
- Row and column address multiplex widths can be changed.
- Waits (0 to 3 waits) can be inserted between the bank active command and the read/write command.
- Supports CBR refresh and CBR self-refresh.

# 5.3.2 SDRAM connection

An example of connection to SDRAM is shown below.

## Figure 5-6. Example of Connection to SDRAM

### 5.3.3 Address multiplex function

Depending on the value of the SAWn0 and SAWn1 bits in SDRAM configuration register n (SCRn), the row address output in the SDRAM cycle is multiplexed as shown in Figure 5-7 (a) (n = 1, 3, 4, 6). Depending on the value of the SSOn0 and SSOn1 bits, the column address output in the SDRAM cycle is multiplexed as shown in Figure 5-7 (b) (n = 1, 3, 4, 6). In Figures 5-7 (a) and (b), a0 to a25 indicate the addresses output from the CPU, and A0 to A25 indicate the address pins of the V850E/ME2.

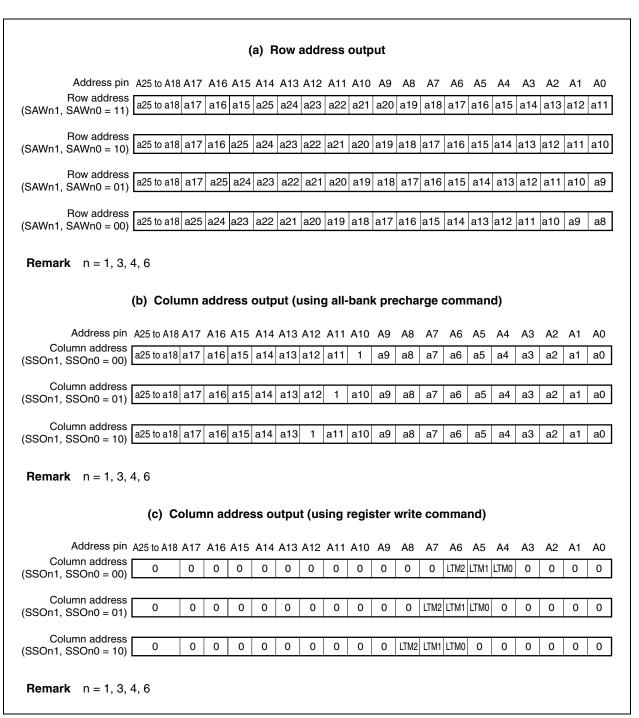

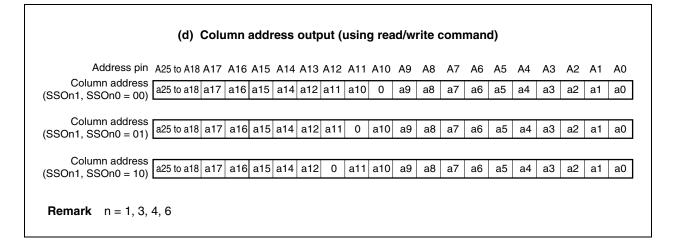

Figure 5-7. Row Address/Column Address Output (1/2)

## 5.3.4 SDRAM configuration registers 1, 3, 4, 6 (SCR1, SCR3, SCR4, SCR6)

These registers specify the number of waits and the address multiplex width. SCRn corresponds to  $\overline{\text{CSn}}$  (n = 1, 3,

4, 6). For example, to connect SDRAM to  $\overline{CS1}$ , set SCR1. These registers can be read or written in 16-bit units.

- Cautions 1. An SDRAM read/write cycle is not generated prior to executing a register write operation. Access SDRAM after reading the value of the SCRn register and confirming that the WCFn bit is set to 1.
  - To write to the SCRn register again following access to SDRAM, clear the MEn bit of the BCT0 and BCT1 registers to 0, and then set it to 1 again before performing access (n = 0 to 6).
  - 3. Do not execute continuous instructions to write to the SCRn register. Be sure to insert another instruction between commands to write to the SCRn register.

# 5.3.5 SDRAM access

During power-on or a refresh operation, the all-bank precharge command is always issued for SDRAM. When accessing SDRAM after that, therefore, the active command and read/write command are issued in that order (see <1> in Figure 5-8).

If a page change occurs following this, the precharge command, active command, and read/write command are issued in that order (see <2> in Figure 5-8).

If a bank change occurs, the active command and read/write command for the bank to be accessed next are issued in that order. Following this read/write command, the precharge command for the bank that was accessed before the bank currently being accessed will be issued (see <3> in Figure 5-8).

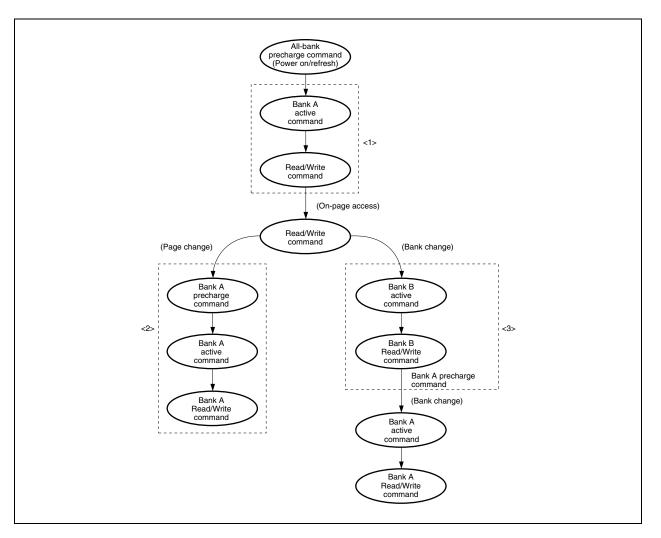

Figure 5-8. State Transition of SDRAM Access

## (1) SDRAM single read cycle

The SDRAM single read cycle is a cycle for reading from SDRAM by executing a load instruction (LD) for the SDRAM area, by fetching an instruction, or by 2-cycle DMA transfer.

In the SDRAM single read cycle, the active command (ACT) and read command (RD) are issued to SDRAM in that order. During on-page access, however, only the read command is issued and the precharge command and active command are not issued. When a page change occurs in the same bank, the precharge command (PRE) is issued before the active command.

A one-state T0 cycle is always inserted immediately before all read commands activated by the CPU.

The number of idle states (TI) set by the bus cycle control register (BCC) are inserted after the read cycle (no idle states are inserted, however, if BCn1 and BCn0 are 00) (n = 1, 3, 4, 6). The timing charts of the SDRAM single read cycle are shown below.

Caution When executing a write access to SRAM or external I/O after read accessing SDRAM, data conflict may occur depending on the SDRAM data output float delay time. In such a case, avoid data conflict by inserting an idle state in the SDRAM space via a setting in the BCC register.

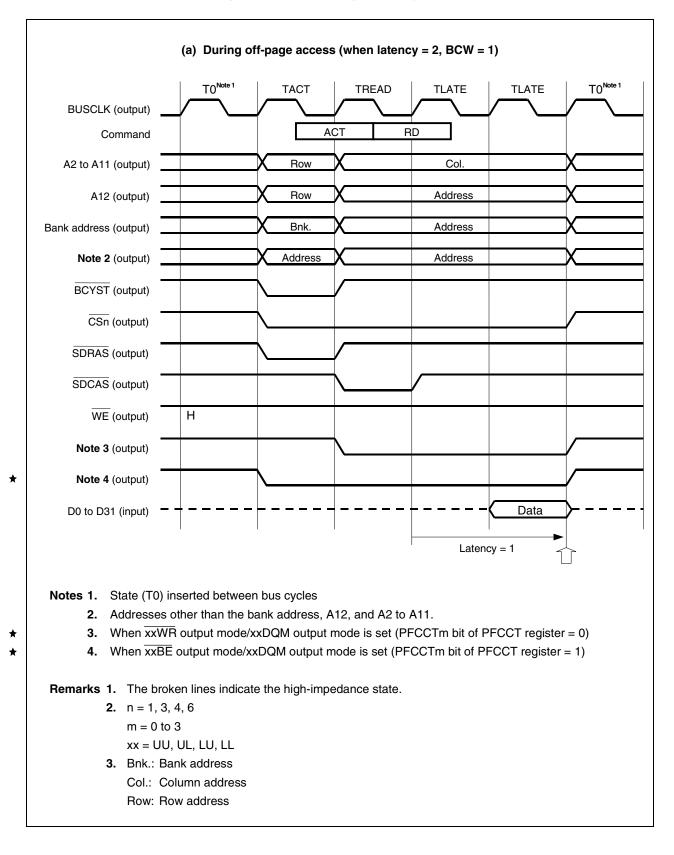

Figure 5-9. SDRAM Single Read Cycle (1/5)

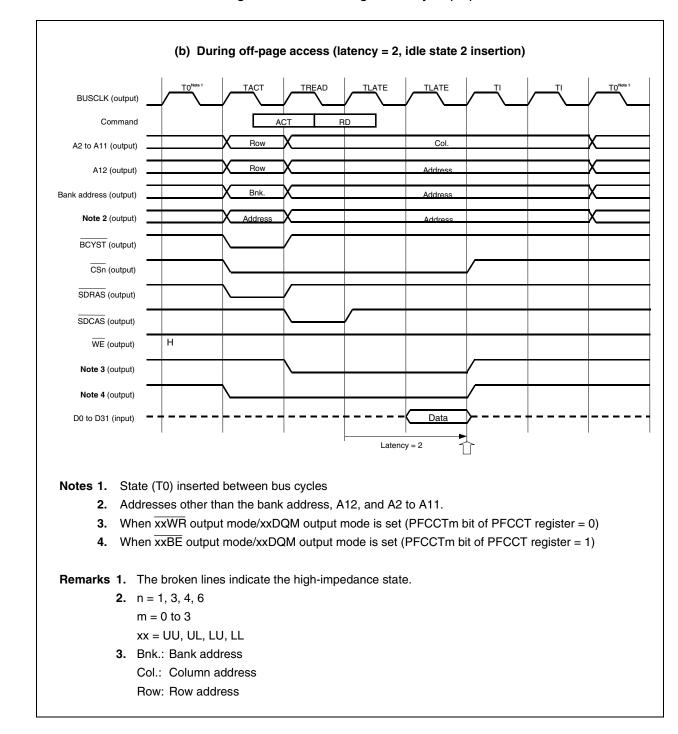

Figure 5-9. SDRAM Single Read Cycle (2/5)

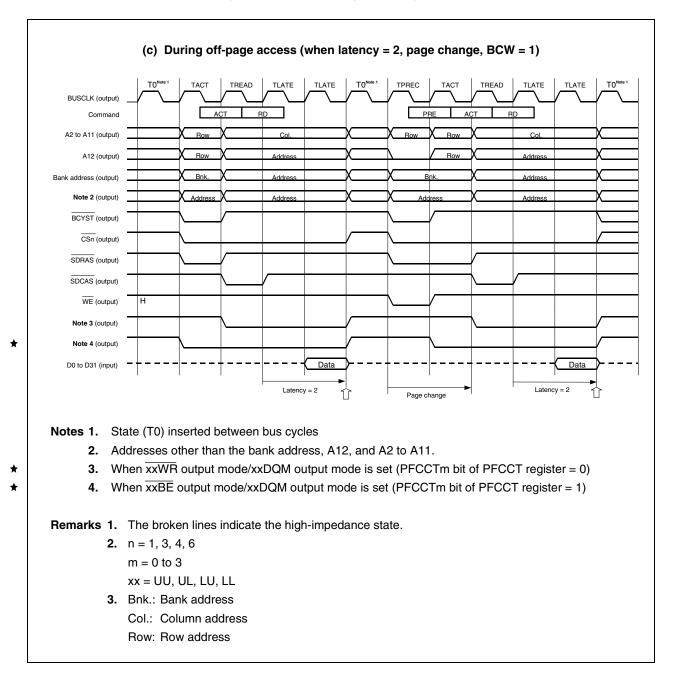

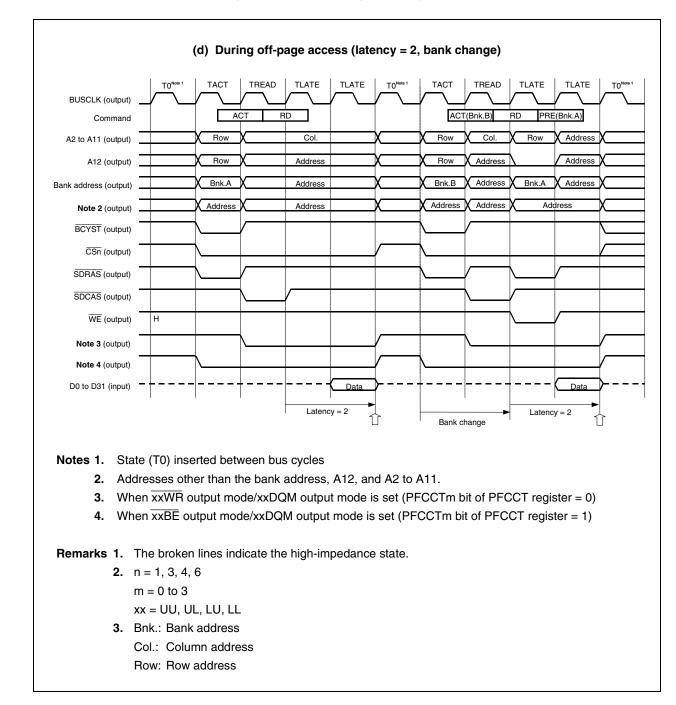

Figure 5-9. SDRAM Single Read Cycle (3/5)

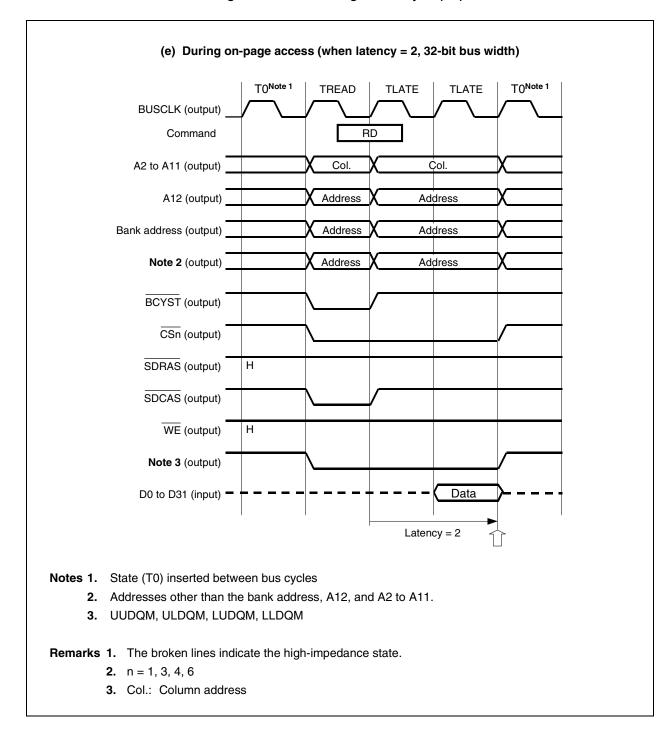

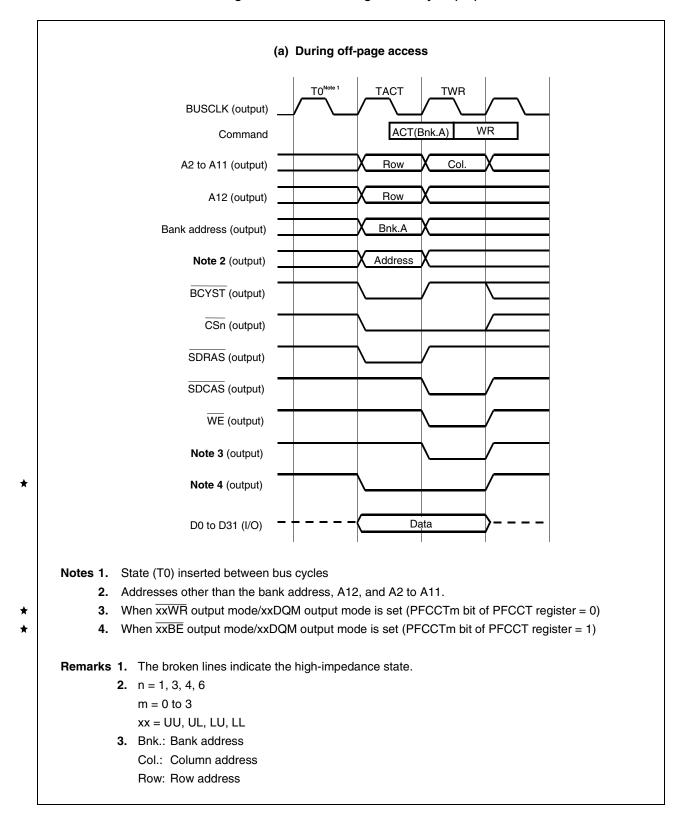

Figure 5-9. SDRAM Single Read Cycle (5/5)

#### (2) SDRAM single write cycle

The SDRAM single write cycle is a cycle for writing to SDRAM by executing a write instruction (ST) for the SDRAM area or by 2-cycle DMA transfer.

In the SDRAM single write cycle, the active command (ACT) and write command (WR) are issued to SDRAM in that order. During on-page access, however, only the write command is issued and the precharge command and active command are not issued. When a page change occurs in the same bank, the precharge command (PRE) is issued before the active command.

A one-state TW cycle is always inserted immediately before all write commands activated by the CPU. The timing charts of the SDRAM single write cycle are shown below.

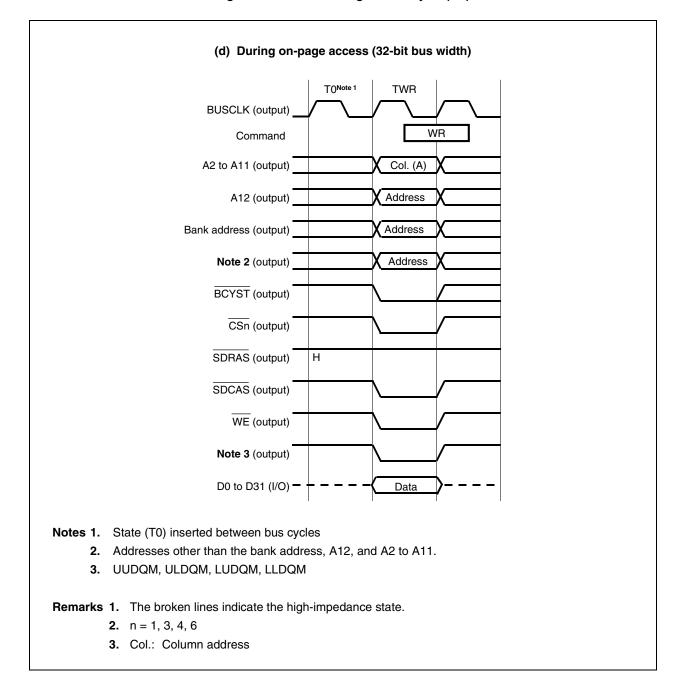

Figure 5-10. SDRAM Single Write Cycle (6/6)

#### (3) SDRAM access timing control

The SDRAM access timing can be controlled by SDRAM configuration register n (SCRn) (n = 1, 3, 4, 6). For details, see **5.3.4** SDRAM configuration registers **1**, **3**, **4**, **6** (SCR1, SCR3, SCR4, SCR6).

Caution Wait control by the  $\overline{WAIT}$  pin is not available during SDRAM access.

#### (a) Number of waits from bank active command to read/write command

The number of wait states from bank active command issue to read/write command issue can be set by setting the BCWn1 and BCWn0 bits of the SCRn register.

BCWn1, BCWn0 = 01B: 1 wait BCWn1, BCWn0 = 10B: 2 waits BCWn1, BCWn0 = 11B: 3 waits

#### (b) Number of waits from precharge command to bank active command

The number of wait states from precharge command issue to bank active command issue can be set by setting the BCWn1 and BCWn0 bits of the SCRn register.

BCWn1, BCWn0 = 01B: 1 wait BCWn1, BCWn0 = 10B: 2 waits BCWn1, BCWn0 = 11B: 3 waits

#### (c) CAS latency setting when read

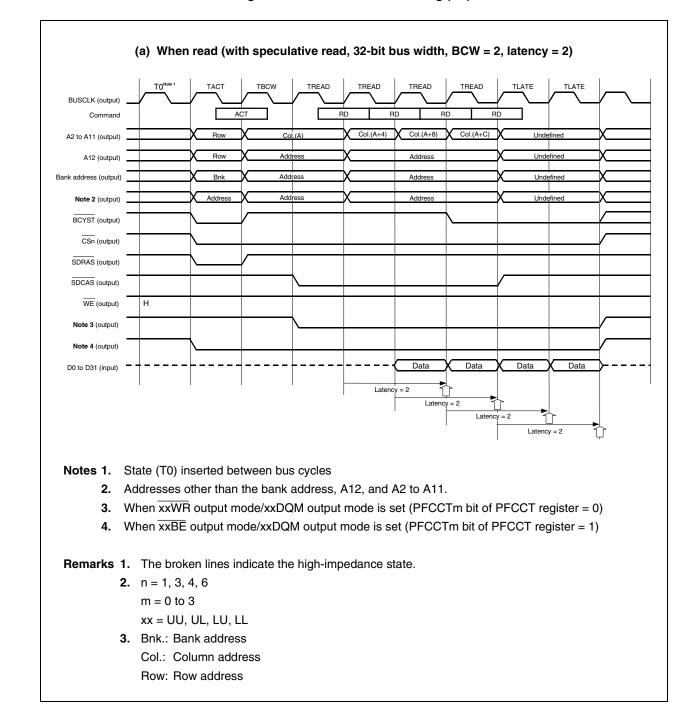

The CAS latency during a read operation can be set by setting the LTMn2 to LTMn0 bits of the SCRn register.

LTMn2 to LTMn0 = 001B: Latency = 1 (setting prohibited during DMA flyby transfer) LTMn2 to LTMn0 = 010B: Latency = 2 LTMn2 to LTMn0 = 011B: Latency = 3

#### (d) Number of waits from refresh command to next command

The number of wait states from refresh command issue to next command issue can be set by setting the BCWn1 and BCWn0 bits of the SCRn register. The number of wait states becomes four times the value set by BCWn1 and BCWn0 bits.

BCWn1, BCWn0 = 01B: 4 waits BCWn1, BCWn0 = 10B: 8 waits BCWn1, BCWn0 = 11B: 12 waits

#### 5.3.6 Refresh control function

The V850E/ME2 can generate a refresh cycle. The refresh cycle is set with SDRAM refresh control registers 1, 3, 4, and 6 (RFS1, RFS3, RFS4, RFS6). RFSn corresponds to  $\overline{CSn}$  (n = 1, 3, 4, 6). For example, to connect SDRAM to  $\overline{CS1}$ , set RFS1.

When another bus master occupies the external bus, the DRAM controller cannot occupy the external bus. In this case, the DRAM controller issues a refresh request to the bus master by changing the REFRQ signal to active (low level).

During a refresh operation, the address bus retains the state it was in just before the refresh cycle.

#### (1) SDRAM refresh control registers 1, 3, 4, 6 (RFS1, RFS3, RFS4, RFS6)

These registers are used to enable or disable a refresh and set the refresh interval. The refresh interval is determined by the following calculation formula.

Refresh interval ( $\mu$ s) = Refresh count clock (T<sub>RCY</sub>) × Interval factor

The refresh count clock and interval factor are determined by the RCCn1 and RCCn0 bits and RIN5n to RIN0n bits, respectively, of the RFSn register.

Note that n corresponds to the register number (1, 3, 4, 6) of SDRAM configuration registers 1, 3, 4, 6 (SCR1, SCR3, SCR4, SCR6).

These registers can be read or written in 16-bit units.

Caution Write to the RFS1, RFS3, RFS4, and RFS6 registers after reset, and then do not change the set values. However, when the SDRAM refresh interval needs to be changed by changing the CKC register set value (internal system clock (fcLK)), the set value of the RFS1, RFS3, RFS4, and RFS6 registers can be changed. For details, refer to Caution 2 in 8.3.1 Clock control register (CKC). Also, do not access an external memory area other than the one for this initialization routine until the initial settings of the RFS1, RFS3, RFS4, and RFS6 registers are complete. However, it is possible to access external memory areas whose initialization settings are complete.

	256/BUSCLK	4 (15.5)	3 (15.4)				

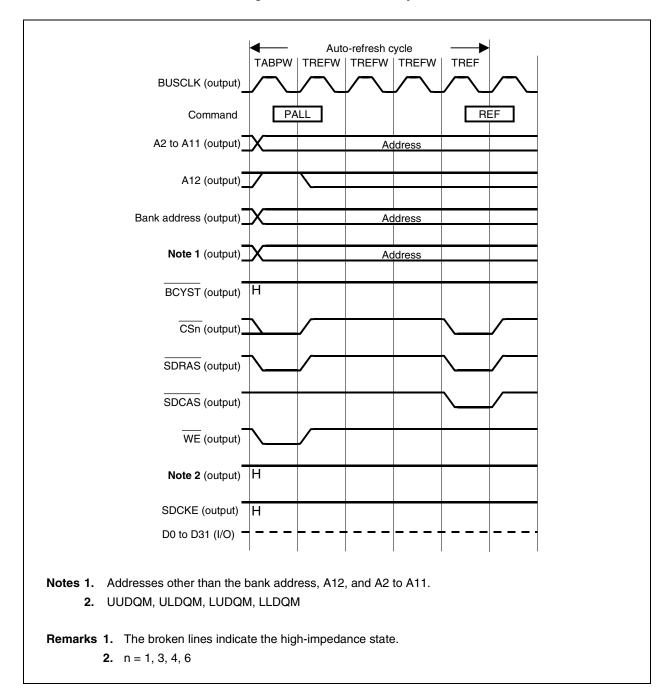

Notes 1. The interval factor is set by bits RINn0 to RINn5 of the RFSn register (n = 1, 3, 4, 6).

2. The values in parentheses are the calculated values for the refresh interval ( $\mu$ s). Refresh interval ( $\mu$ s) = Refresh count clock (T<sub>RCY</sub>) × Interval factor

The V850E/ME2 can automatically generate an auto-refresh cycle and a self-refresh cycle.

#### (2) Auto-refresh cycle

In the auto-refresh cycle, the auto-refresh command (REF) is issued four clocks after the precharge command for all banks (PALL) is issued.

#### (3) Refresh timing

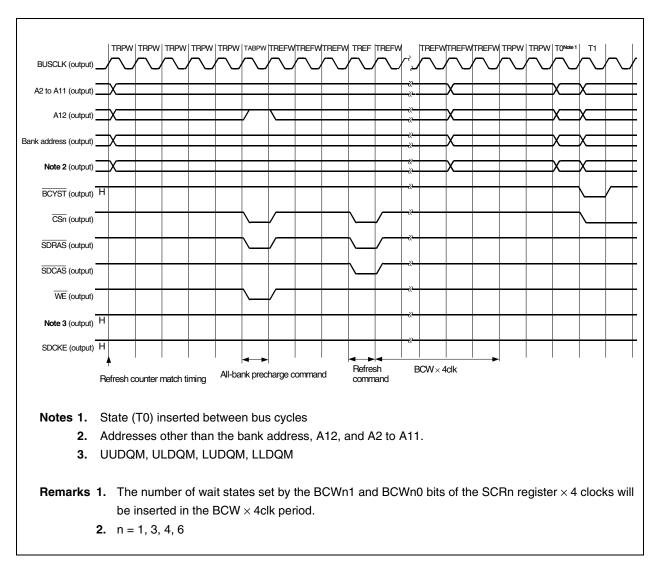

Figure 5-13. CBR Refresh Timing (SDRAM)

#### 5.3.7 Self-refresh control function

In the case of transition to the IDLE or software STOP mode, or if the SELFREF signal becomes active, the DRAM controller generates the self-refresh cycle.

# Cautions 1. When the transition to the self-refresh cycle is caused by SELFREF signal input, releasing the self-refresh cycle is only possible by inputting an inactive level to the SELFREF pin.

2. The internal instruction RAM (only in the read mode) and internal data RAM can be accessed even in the self-refresh cycle. However, access to an on-chip peripheral I/O register or external device is held pending until the self-refresh cycle is cleared.

To release the self-refresh cycle, use one of the three methods below.

#### (1) Release by NMI input

#### (a) In the case of self-refresh cycle in IDLE mode

To release the self-refresh cycle, make the SDRAS and SDCAS signals inactive immediately.

#### (b) In the case of self-refresh cycle in software STOP mode

To release the self-refresh cycle, make the SDRAS and SDCAS signals inactive after stabilizing oscillation.

#### (2) Release by INTP0n0 and INTP0n1 inputs (n = 0 to 3)

#### (a) In the case of self-refresh cycle in IDLE mode

To release the self-refresh cycle, make the SDRAS and SDCAS signals inactive immediately.

#### (b) In the case of self-refresh cycle in software STOP mode

To release the self-refresh cycle, make the SDRAS and SDCAS signals inactive after stabilizing oscillation.

#### (3) Release by RESET input

#### 5.3.8 SDRAM initialization sequence

Be sure to initialize SDRAM when applying power.

- (1) Set the registers of SDRAM (other than SDRAM configuration register n (SCRn)).
  - Bus cycle type configuration registers 0 and 1 (BCT0 and BCT1)
  - Bus cycle control register (BCC)
  - SDRAM refresh control registers 1, 3, 4, 6 (RFS1, RFS3, RFS4, RFS6)
- (2) Set SDRAM configuration registers 1, 3, 4, 6 (SCR1, SCR3, SCR4, SCR6). When writing data to these registers, the following commands are issued for SDRAM in the order shown below.
  - All-bank precharge command
  - Refresh command (8 times)
  - · Command that is used to set a mode register
  - Cautions 1. To set the SCR1, SCR3, SCR4, and SCR6 registers, confirm that the LOCK bit of the lock register (LOCKR) is set to 1, set the CKSSEL bit of the clock source select register (CKS) to 1, and change clock supply to the CPU to SSCG output (see 3.4.10 Initialization sequence).
    - 2. If it is necessary to make the input levels of the UUDQM, ULDQM, LUDQM, and LLDQM pins high until initialization of SDRAM is completed, do not change the set values of the PFCCT3 to PFCCT0 bits of the PFCCT register and do not write the external device until initialization of SDRAM is completed.

Figures 5-15 and 5-16 show examples of the SDRAM mode register setting timing.

### CHAPTER 6 DMA FUNCTIONS (DMA CONTROLLER)

The V850E/ME2 includes a direct memory access (DMA) controller (DMAC) that executes and controls DMA transfer.

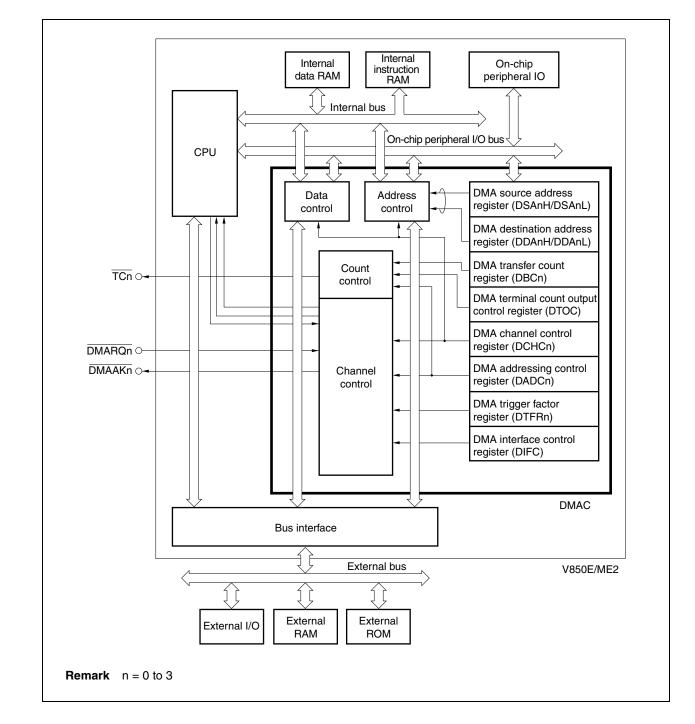

The DMAC controls data transfer between memory and I/O, or among memories, based on requests by interrupts from on-chip peripheral I/O (serial interface, real-time pulse unit, and A/D converter) or DMA requests issued by the DMARQ0 to DMARQ3 pins, software triggers, or USB. Memory refers to the internal instruction RAM, internal data RAM, or external memory. However, the internal instruction RAM can be used only as the transfer destination.

#### 6.1 Features

- 4 independent DMA channels
- Transfer unit: 8/16/32 bits
- Maximum transfer count: 65,536 (2<sup>16</sup>)
- Two types of transfer
  - Flyby (1-cycle) transfer
  - 2-cycle transfer
- Three transfer modes
  - Single transfer mode
  - Single-step transfer mode
  - Block transfer mode
- Transfer requests
  - Request by interrupts from on-chip peripheral I/O (serial interface, real-time pulse unit, A/D converter)
  - Requests via DMARQ0 to DMARQ3 pin input
  - Requests by software trigger
  - Requests by USB (only in the single transfer mode)
- Transfer objects
  - Memory  $\leftrightarrow$  I/O
  - Memory  $\leftrightarrow$  memory
- DMA transfer end output signals (TC0 to TC3)
- Next address setting function

### 6.3 Control Registers

#### 6.3.1 DMA source address registers 0 to 3 (DSA0 to DSA3)

These registers are used to set the DMA transfer source address (28 bits) for DMA channel n (n = 0 to 3). They are divided into two 16-bit registers, DSAnH and DSAnL.

Since these registers are configured as 2-stage FIFO buffer registers, a new transfer source address for DMA transfer can be specified during DMA transfer (see **6.8 Next Address Setting Function**). In this case, the newly set value of the DSAn register is transferred to the slave register and becomes valid only when DMA transfer has been completed normally and the TCn bit of the DCHCn register is set to 1, or when the INITn bit of the DCHCn register is set to 1 (n = 0 to 3). However, the set value of the DSAn register is invalid even when the Enn bit of the DCHCn register is cleared to 0 to disable DMA transfer and then the DSAn register is set.

When flyby transfer is specified with the TTYPn bit of DMA addressing control register n (DADCn), the external memory addresses are set by the DSAn register. At this time, the setting of DMA destination address register n (DDAn) is ignored (n = 0 to 3).

#### (1) DMA source address registers 0H to 3H (DSA0H to DSA3H)

These registers can be read or written in 16-bit units.

Be sure to clear bits 14 to 12 to 0. If they are set to 1, the operation is not guaranteed.

2. Do not set the DSAnH register while DMA transfer is suspended.

# Cautions 1. When setting an address of a peripheral I/O register for the source address, be sure to specify an address between FFFF000H and FFFFFFH. An address of the peripheral I/O register image (3FFF000H to 3FFFFFFH) must not be specified.

#### 6.3.2 DMA destination address registers 0 to 3 (DDA0 to DDA3)

These registers are used to set the DMA transfer destination address (28 bits) for DMA channel n (n = 0 to 3). They are divided into two 16-bit registers, DDAnH and DDAnL.

Since these registers are configured as 2-stage FIFO buffer registers, a new transfer destination address for DMA transfer can be specified during DMA transfer (see **6.8 Next Address Setting Function**). In this case, the newly set value of the DDAn register is transferred to the slave register and becomes valid only when DMA transfer has been completed normally and the TCn bit of the DCHCn register is set to 1, or when the INITn bit of the DCHCn register is set to 1 (n = 0 to 3). However, the set value of the DDAn register is invalid even when the Enn bit of the DCHCn register is cleared to 0 to disable DMA transfer and then the DDAn register is set.

When flyby transfer is specified with the TTYPn bit of DMA addressing control register n (DADCn), the setting of DMA destination address register n (DDAn) is ignored.

#### (1) DMA destination address registers 0H to 3H (DDA0H to DDA3H)

These registers can be read or written in 16-bit units.

Be sure to clear bits 14 to 12 to 0. If they are set to 1, the operation is not guaranteed.

# Cautions 1. When setting an address of a peripheral I/O register for the destination address, be sure to specify an address between FFFF000H and FFFFFFH. An address of the peripheral I/O register image (3FFF000H to 3FFFFFFH) must not be specified.

2. Do not set the DDAnH register while DMA transfer is suspended.

#### 6.3.3 DMA transfer count registers 0 to 3 (DBC0 to DBC3)

These 16-bit registers are used to set the byte transfer count for DMA channel n (n = 0 to 3). They store the remaining transfer count during DMA transfer.

Since these registers are configured as 2-stage FIFO buffer registers, a new DMA byte transfer count for DMA transfer can be specified during DMA transfer (see **6.8 Next Address Setting Function**). In this case, the newly set value of the DBCn register is transferred to the slave register and becomes valid only when DMA transfer has been completed normally and the TCn bit of the DCHCn register is set to 1, or when the INITn bit of the DCHCn register is set to 1 (n = 0 to 3). However, the set value of the DBCn register is invalid even when the Enn bit of the DCHCn register is cleared to 0 to disable DMA transfer and then the DBCn register is set.

These registers are decremented by 1 for each transfer, and transfer ends when a borrow occurs.

These registers can be read or written in 16-bit units.

# Cautions 1. If the DBCn register is read during DMA transfer after a terminal count has occurred without the register being overwritten, the value set immediately before the DMA transfer will be read out (0000H will not be read, even if DMA transfer has ended).

	۰.

# 2. Do not set the DBCn register while DMA transfer is suspended.

#### 6.3.4 DMA addressing control registers 0 to 3 (DADC0 to DADC3)

These 16-bit registers are used to control the DMA transfer mode for DMA channel n (n = 0 to 3). These registers cannot be accessed during DMA operation.

These registers can be read or written in 16-bit units.

+

\*

Be sure to clear bits 13 to 8 to 0. If they are set to 1, the operation is not guaranteed.

Cautions 1. The DSn1 and DSn0 bits set how many bits of data are to be transferred.

When 8-bit data is set (DSn1 and DSn0 bits = 00), the lower bytes of the data bus (D0 to D7) are not always used.

If the transfer data size is set to 16 bits, transfer is always started from an address with the lowest bit of the address aligned to "0". If the data size is set to 32 bits, transfer is started from an address with the lowest 2 bits of the address aligned to "0". In this case, transfer cannot be started from an odd address.

- Set the DADCn register at the following timing while the target DMA channel is in operation or is not suspended (the operation is not guaranteed if the register is set at any other timing).
  - · Period from system reset to generation of the first DMA transfer request
  - Period from completion of DMA transfer (after generation of terminal count) to generation of the next DMA transfer request
  - Period from forced termination of DMA transfer (after the INITn bit of the DCHCn register is set to 1) to generation of the next DMA transfer request
- 3. Do not set flyby transfer via the TTYPn bit if all the following conditions are satisfied (n = 0 to 3).
  - BMC register = 00H
  - FWn2 to FWn0 bits of FWC register = 000
  - FIn1 to FIn0 bits of FIC register = 00
  - ACn1 and ACn0 bits of the CSn space subject to flyby transfer by the ASC register = 00 (during transfer to/from SRAM)

## 6.3.5 DMA channel control registers 0 to 3 (DCHC0 to DCHC3)

These 8-bit registers are used to control the DMA transfer operating mode for DMA channel n (n = 0 to 3). These registers can be read or written in 8-bit or 1-bit units. (However, bit 7 is read only and bits 2 and 1 are write only. If bits 2 and 1 are read, the read value is always 0.)

Be sure to clear bits 6 to 4 to 0. If they are set to 1, the operation is not guaranteed.

- Cautions 1. During a 2-cycle transfer that performs a write operation on the external device, the write operation on the external device may not be completed even if the TCn bit of the DCHCn register is set to 1 (DMA transfer completion) by the write buffer function. Recognize completion of the write operation on the external device as follows, if necessary.
  - Monitor the signal of the TCn pin (the TCn pin becomes active in synchronization with the write operation on the external device).
  - After it has been detected that the TCn bit of the DCHCn register is set to 1, write the same value as that set to the LBC0 or LBC1 register. When this dummy write is completed, completion of an access from the write buffer to the external device can be recognized. If the set value of the LBC0 or LBC1 register is rewritten when a dummy write is executed, the operation is not guaranteed.
  - 2. Setting the MLEn bit to 1 is valid only when DMA transfer (hardware DMA) is started by DMARQn pin input or an interrupt from the on-chip peripheral I/O. To start DMA transfer by setting the STGn bit to 1 (software DMA), read the TCn bit and confirm that it is set to 1, and then set the STGn bit to 1.
  - 3. Set the MLEn bit at the following timing while the target DMA channel is in operation or is not suspended (the operation is not guaranteed if the register is set at any other timing).
    - Period from system reset to generation of the first DMA transfer request
    - Period from completion of DMA transfer (after generation of terminal count) to generation of the next DMA transfer request
    - Period from forced termination of DMA transfer (after the INITn bit is set to 1) to generation of the next DMA transfer request
  - 4. If DMA transfer is forcibly terminated in the last transfer cycle with the MLEn bit set to 1, the same operation as that performed when transfer is completed is performed (the TCn bit is set to 1). (The Enn bit is cleared to 0 on completion of forced termination, regardless of the value of the MLEn bit.)

In this case, the TCn bit must be read (cleared to 0) in addition to setting the Enn bit when the next DMA transfer is requested.

- 5. Do not set the Enn and STGn bits while DMA is suspended.
- 6. Each bit is updated upon completion of DMA transfer (at terminal count) with the Enn bit cleared to 0 and the TCn bit set to 1 in that order. While the statuses of the TCn and Enn bits are being polled, therefore, values indicating the status of "transfer not completed and prohibited" (TCn bit = 0 and Enn bit = 0) may be read if the DCHCn register is read while each bit is being updated.

\*

\*

Cautions 7. The TCn bit does not have to be read (cleared to 0) on completion of DMA transfer (on generation of the terminal count) only if the following two conditions are satisfied. If either of the conditions is not satisfied, be sure to read the TCn bit (cleared to 0) before the next DMA transfer request is generated.

\*

- If the MLEn bit is set to 1 upon completion of DMA transfer (at terminal count)
- If the source that starts the next DMA transfer is an external pin (DMARQn)

If these two conditions are not satisfied, the operation is not guaranteed if the next DMA transfer request is generated with the TCn bit set to 1.

3	MLEn	If this bit is set to 1 when DMA transfer is complete (at terminal count output), the Enn bit is not cleared to 0 and the DMA transfer enable state is retained. If the next DMA transfer startup factor is input from the DMARQn pin or is an interrupt from the on-chip peripheral I/O (hardware DMA), the DMA transfer request is acknowledged even if the TCn bit is not read. If the next DMA transfer startup factor is input by setting the STGn bit to 1 (software DMA), the DMA transfer request is acknowledged if the TCn bit is read and cleared to 0. If this bit is cleared to 0 when DMA transfer is complete (at terminal count output), the Enn bit is cleared to 0 and the DMA transfer disable state is entered. At the next DMA request, the Enn bit must be set to 1 and the TCn bit read.
2	INITn	If this bit is set to 1 during DMA transfer or while DMA transfer is suspended, DMA transfer is forcibly terminated.
1	STGn	If this bit is set to 1 in the DMA transfer enable state (TCn bit = 0, Enn bit = 1), DMA transfer is started.

## 6.3.6 DMA terminal count output control register (DTOC)

The DMA terminal count output control register (DTOC) is an 8-bit register that controls the terminal count output from each DMA channel and DMA transfer during NMI input. Terminal count signals from each DMA channel can be brought together and output from the  $\overline{\text{TCO}}$  pin.

This register can be read or written in 8-bit or 1-bit units.

#### 6.3.7 DMA trigger factor registers 0 to 3 (DTFR0 to DTFR3)

These 8-bit registers are used to control the DMA transfer start trigger through interrupt requests from on-chip peripheral I/O.

The interrupt requests set by these registers serve as DMA transfer startup factors.

These registers can be read or written in 8-bit or 1-bit units. However, only bit 7 (DFn) can be read or written in 1bit units.

Cautions 1. To change the setting of the DTFRn register, be sure to stop the DMA operation.

- 2. An interrupt request input in the standby mode (IDLE or software STOP mode) cannot be a DMA transfer start factor.
- - 3. If the factor of starting DMA transfer is changed by using the IFCn6 to IFCn0 bits, be sure to clear the DFn bit to 0 using the instruction immediately after.
  - 4. When a transmission completion interrupt request signal (UBTIT0 or UBTIT1) of UARTB is used as the factor of starting DMA transfer, the factor of starting DMA transfer that is triggered by the interrupt request signal generated when the last transmission was completed is retained. In this case, clear the DFn bit to 0 to clear the DMA transfer request.

**Remark** n = 0 to 3

The relationship between the  $\overline{\text{DMARQn}}$  signal and the interrupt source that serves as a DMA transfer trigger is as follows (n = 0 to 3).

**Remark** If an interrupt request is specified as the DMA transfer start factor, an interrupt request will be generated if DMA transfer starts. To prevent an interrupt from being generated, mask the interrupt by setting the interrupt request control register. DMA transfer starts even if an interrupt is masked.

For the level detection mode (IFCn6 to IFCn0 bits = 0000000) and edge detection mode (IFCn6 to IFCn0 bits = 0000001) of the  $\overline{DMARQn}$  pin input, see **Figures 6-8** to **6-10** (n = 0 to 3).

#### ★ (1) DMA request detection function

The V850E/ME2 has a level detection mode and an edge detection mode as functions to sample the  $\overline{\text{DMARQn}}$  pin (n = 0 to 3). The level detection mode also has a mask mode in which sampling the DMA request is masked.

#### (a) Level detection mode (IFCn6 to IFCn0 bits = 0000000)

In this mode, handshaking of the DMARQn and DMAAKn signals can be executed at high speeds. In the single transfer mode, deassert the DMARQn signal for the duration of twice the internal system clock from the rising edge of the DMAAKn signal, in order not to start the DMA transfer cycle next to that currently under execution. If the DMARQn signal is active for the duration of twice the internal system clock, the next DMA request is recognized. In the 2-cycle transfer mode, however, the active period of the DMAAKn signal may be shortened depending on the combination of the transfer source and transfer destination (Min.: 2 × internal system clock). Consequently, if the inactive timing of the DMARQn signal is generated from the falling edge of the DMAAKn signal, for example, the timing may be four times the internal system clock at the shortest.

For the active width of the DMAAKn signal for 2-cycle transfer, refer to **Table 6-4** Minimum Value of **Active Width of DMAAKn Signal for 2-Cycle Transfer**.

<1> Mask mode (IFCn6 to IFCn0 bits = 0000000 and DRMKn bit of DIFC register = 1)

This mode is used to establish handshaking of the  $\overline{\text{DMARQn}}$  and  $\overline{\text{DMAAKn}}$  signals in synchronization with BUSCLK in the level detection mode. In the single transfer mode, deassert the  $\overline{\text{DMARQn}}$  signal within 3 × BUSCLK after sampling the rising edge of the  $\overline{\text{DMAAKn}}$  signal, in order not to start the DMA transfer cycle next to that currently under execution. When the mask mode is set, sampling the DMA request is always masked for the duration of 3 × BUSCLK period from the rising edge of the  $\overline{\text{DMARQn}}$  signal, regardless of the division ratio of BUSCLK (set by the BMC register).

## (b) Edge detection mode (IFCn6 to IFCn0 bits = 0000001)

This mode uses the falling edge of the  $\overline{\text{DMARQn}}$  signal as a DMA request. It realizes handshaking of the  $\overline{\text{DMARQn}}$  and  $\overline{\text{DMAAKn}}$  signals at a speed much lower than that when the mask mode is used. However, note that the falling edge of the  $\overline{\text{DMARQn}}$  signal is ignored, even if input, while the  $\overline{\text{DMAAKn}}$  signal is active.

For the detailed timing in each mode, refer to CHAPTER 17 ELECTRICAL SPECIFICATIONS (TARGET VALUES).

## 6.3.8 DMA interface control register (DIFC)

Г

This 8-bit register controls the active width of the  $\overline{DMAAKn}$  signal of each DMA channel and controls the mask function (DMA mask mode) of the  $\overline{DMARQn}$  signal (n = 0 to 3).

This register can be read or written in 8-bit or 1-bit units.

## 6.4 Transfer Modes

#### 6.4.1 Single transfer mode

In single transfer mode, the DMAC releases the bus at each byte/halfword/word transfer. If there is a subsequent DMA transfer request, transfer is performed again once. This operation continues until a terminal count occurs.

When the DMAC has released the bus, if another higher priority DMA transfer request is issued, the higher priority DMA request always takes precedence. If other DMA transfer request with the lower priority occurs one clock after single transfer has been completed, however, this request does not take precedence even if the previous DMA transfer request signal with the higher priority remains active. DMA transfer with the lower priority newly request is executed after the CPU bus has been released.

Figures 6-1 to 6-4 show examples of single transfer.

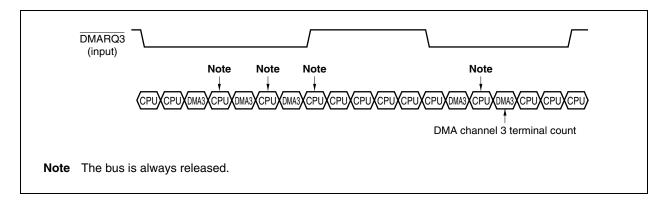

Figure 6-2 shows an example of a single transfer in which a higher priority DMA request is issued. DMA channels 0 to 2 are in the block transfer mode and channel 3 is in the single transfer mode.

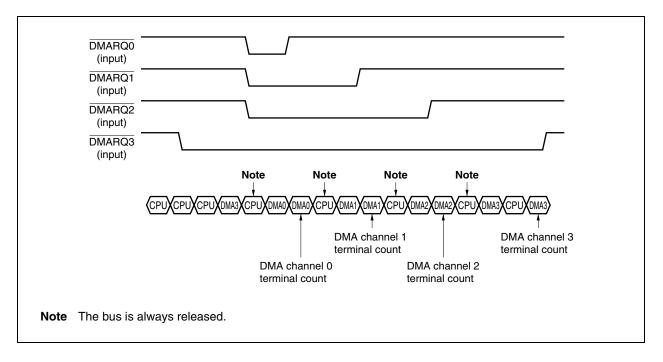

Figure 6-2. Single Transfer Example 2

Figure 6-3 is an example of single transfer where a DMA transfer request with the lower priority is issued one clock after single transfer has been completed. DMA channels 0 and 3 are used for single transfer. If two DMA transfer request signals become active at the same time, two DMA transfer operations are alternately executed.

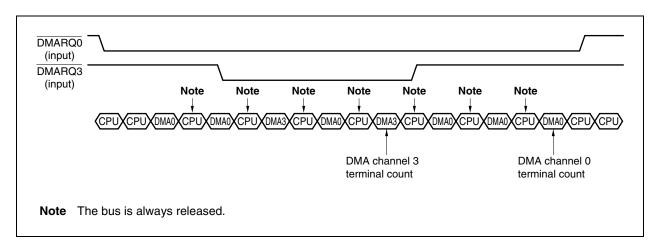

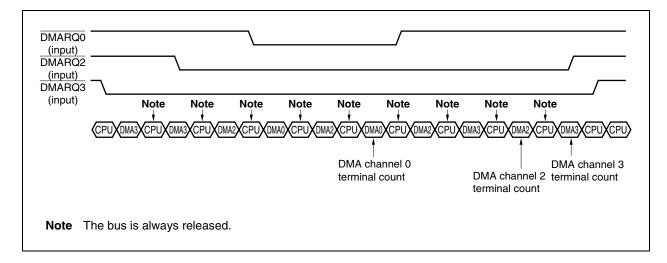

Figure 6-4 is an example of single transfer where two or more DMA transfer requests with the lower priority are issued one clock after single transfer has been completed. DMA channels 0, 2, and 3 are used for single transfer. If three or more DMA transfer request signals become active at the same time, two DMA transfer operations are alternately executed, always starting from the one with the highest priority.

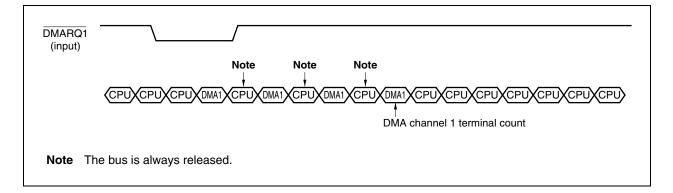

#### 6.4.2 Single-step transfer mode

In single-step transfer mode, the DMAC releases the bus at each byte/halfword/word transfer. If there is a subsequent DMA transfer request signal (DMARQ0 to DMARQ3), transfer is performed again. This operation continues until a terminal count occurs.

When the DMAC has released the bus, if another higher priority DMA transfer request is issued, the higher priority DMA request always takes precedence.

The following shows an example of a single-step transfer. Figure 6-6 shows an example of single-step transfer made in which a higher priority DMA request is issued. DMA channels 0 and 1 are in the single-step transfer mode.

Figure 6-5. Single-Step Transfer Example 1

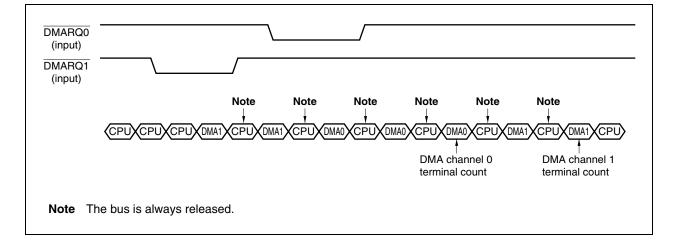

Figure 6-6. Single-Step Transfer Example 2

#### 6.4.3 Block transfer mode

In the block transfer mode, once transfer starts, the DMAC continues the transfer operation without releasing the bus until a terminal count occurs. No other DMA requests are acknowledged during block transfer.

After the block transfer ends and the DMAC releases the bus, another DMA transfer can be acknowledged. The bus cycle of the CPU is not inserted during block transfer, but bus hold and refresh cycles are inserted in between DMA transfer operations.

The following shows an example of block transfer in which a higher priority DMA request is issued. DMA channels 2 and 3 are in the block transfer mode.

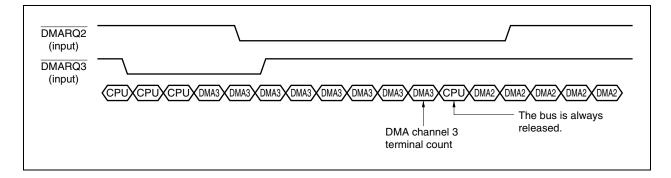

Figure 6-7. Block Transfer Example

## 6.5 Transfer Types

#### 6.5.1 2-cycle transfer

In 2-cycle transfer, data transfer is performed in two cycles, a read cycle (source to DMAC) and a write cycle (DMAC to destination).

In the first cycle, the source address is output and reading is performed from the source to the DMAC. In the second cycle, the destination address is output and writing is performed from the DMAC to the destination.

#### Caution An idle cycle of 1 to 2 clocks is always inserted between a read cycle and a write cycle.

2. For details, refer to Table 6-4 Minimum Value of Active Width of DMAAKn Signal for 2-Cycle Transfer.

The bus configuration is as shown below.

The active width of the DMAAKn signal output by the DMA controller is from the beginning of a read operation by the DMA controller to the end of a write operation (n = 0 to 3). The  $\overline{\text{DMAAKn}}$  signal is not asserted in a cycle used to write/read the internal data RAM.

The active width of the  $\overline{\text{DMAAKn}}$  signal for each DMA transfer is shown below.

#### Table 6-2. Active Width of DMAAKn Signal for 2-Cycle Transfer

Remark (): Cycle without speculative reading or in case of speculative read miss-hit

Therefore, the correlation between external access during 2-cycle transfer (execution to external I/O/external memory) and the active width of the DMAAKn signal is as follows.

# Table 6-3. Correlation Between External Access (Execution to External I/O/External Memory) and Active Width of DMAAKn Signal

		Speculative Read Function	Transfer Destination			
			External I/O/ External Memory	On-Chip Peripheral I/O	Internal Data RAM	Internal Instruction RAM
Transfer source	External I/O/external memory	None	$\checkmark$	$\checkmark$	$\checkmark$	$\checkmark$
	On-chip peripheral I/O		× (a)	_	_	-
	Internal data RAM		× (a)	-	_	_
	External I/O/external memory	Provided	× (b)	× (c)	× (c)	× (c)
	On-chip peripheral I/O		× (a)	_	_	-
	Internal data RAM		× (a)	-	-	-

**Remarks**  $\sqrt{}$ : The DMAAKn signal is asserted while DMA access to/from external I/O/external memory is being executed.

- X: The DMAAKn signal may not be asserted while DMA access to/from external I/O/external memory is being executed.
- (a): Handshaking of the DMARQn and DMAAKn signals may be completed before a write operation to the external I/O or external memory is executed.

As soon as data has been transferred to the write buffer ( $<4> \rightarrow <1> \rightarrow <6>$  or  $<1> \rightarrow <6>$ ), assertion of the DMAAKn signal ends. If data of three buffers has already been stored in the write buffer separately, data transferred by DMA is stored in the fourth buffer. Subsequently, when a write operation of the stored data has taken place three times, transfer to the external I/O or external memory targeted by the last DMAAKn signal is executed ( $<6> \rightarrow <7>$ ).

(b): Handshaking of the DMARQn and DMAAKn signals may be completed if a read operation from the external I/O or external memory (DMA access) has been completed before handshaking of the DMARQn and DMAAKn signals is completed, or before a write operation to the external I/O or external memory is executed.

The active state of the  $\overline{\text{DMAAKn}}$  signal ends as soon as data has been transferred to the write buffer (<5>  $\rightarrow$  <1>  $\rightarrow$  <6>). If speculative reading hits, data is read from the external I/O or external memory when speculative reading has been completed. Therefore, a read operation from the external I/O or external memory (<7>  $\rightarrow$  <5>) is executed before the  $\overline{\text{DMAAKn}}$  signal. While data is being transferred from the speculative read buffer to the write buffer (<5>  $\rightarrow$  <1>  $\rightarrow$  <6>) after that, the  $\overline{\text{DMAAKn}}$  signal is asserted. For example, if data of three buffers has already been stored in the write buffer, data transferred by DMA is stored in the fourth buffer. After that, transfer to the external I/O or external memory (<6>  $\rightarrow$  <7>) targeted by the last  $\overline{\text{DMAAKn}}$  signal is executed when a write operation of the stored data has taken place three times.

(c): A read operation from the external I/O or external memory (DMA access) may be completed before handshaking of the DMARQn and DMAAKn signals is completed.
If speculative reading hits, because the data has already been transferred from the external I/O or external memory to the speculative read buffer (<7> → <5>), execution to the external I/O or external memory (DMA access) will have already been completed while the DMAAKn signal was asserted (<5> → <1> → (<2>, <3> or <4>)).

## (2) DMAAKn signal active width extension function

The DMAAKn signal is output in synchronization with the internal bus cycle during 2-cycle transfer, and is not synchronized with the external bus cycle (n = 0 to 3). The DMA cycle differs depending on the configuration subject to DMA transfer (refer to **6.5.1 (1) Timing of DMARQn and DMAAKn signals for 2-cycle transfer**). Depending on the target of DMA transfer, the configuration may allow the DMAAKn signal to be asserted only for the duration of two internal system clocks. In this case, assertion of the DMAAKn signal may not be sampled with BUSCLK if the internal system clock is divided and the bus clock (BUSCLK) is used (e.g., BMC register = 02H: internal system clock divided by three).

To sample assertion of the DMAAKn signal with BUSCLK, extend the active width of the DMAAKn signal by using the DAKEBC bit of the DTOC register and DAKEn bit of the DIFC register.

The minimum value of the active width of the DMAAKn during 2-cycle transfer is shown in the table below.

		Speculative	Transfer Destination					
		Read Function	External I/O/ External Memory	On-Chip Peripheral I/O	Internal Data RAM	Internal Instruction RAM

Table 6-4. Minimum Value of Active Width of DMAAKn Signal During 2-Cycle Transfer

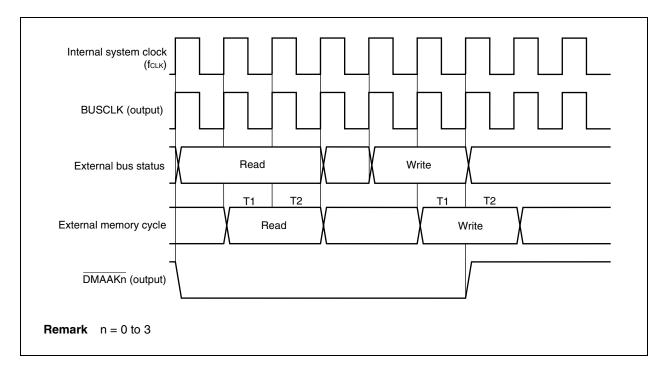

Caution The function to extend the active width of the DMAAKn signal can be used only during 2-cycle transfer (n = 0 to 3). It cannot be used during flyby transfer. The operation is not guaranteed if it is used during flyby transfer. During flyby transfer, the DMAAKn signal synchronized with the bus cycle is output.

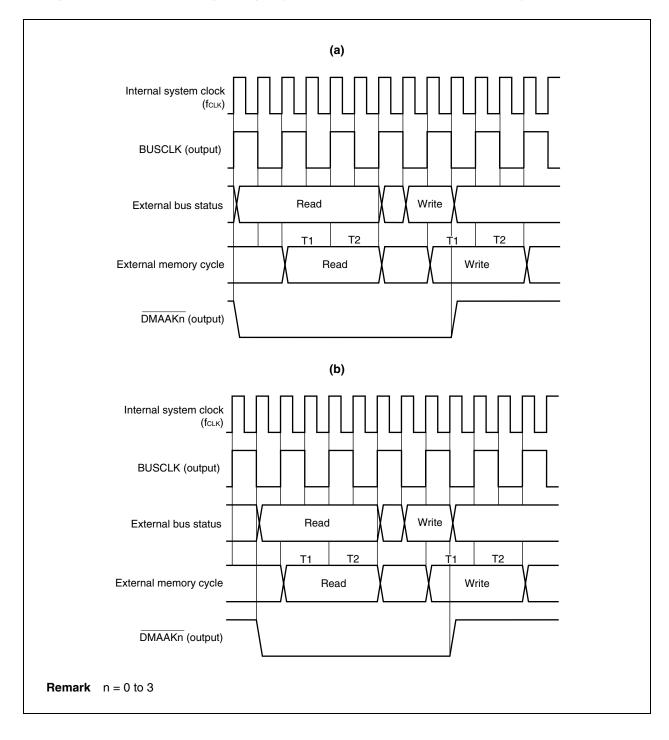

Remark i: Number of wait cycles set by VSWC register

## ★ (3) Outline of 2-cycle transfer timing

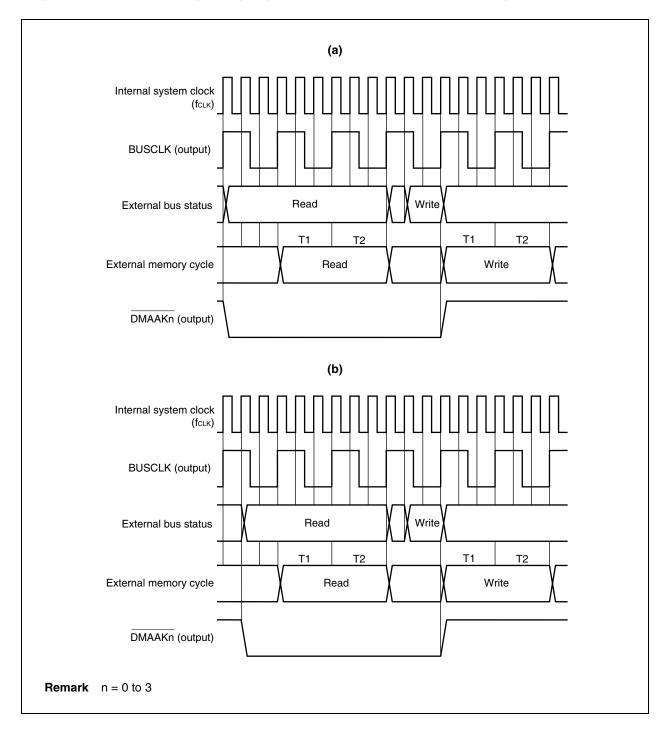

The timing of 2-cycle transfer is outlined below.

## Figure 6-14. Outline of Timing During 2-Cycle Transfer (SRAM → SRAM): Divided by 1 (0 SRAM Waits)

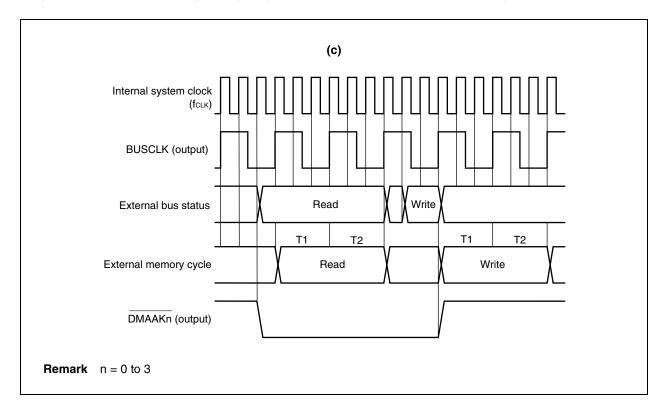

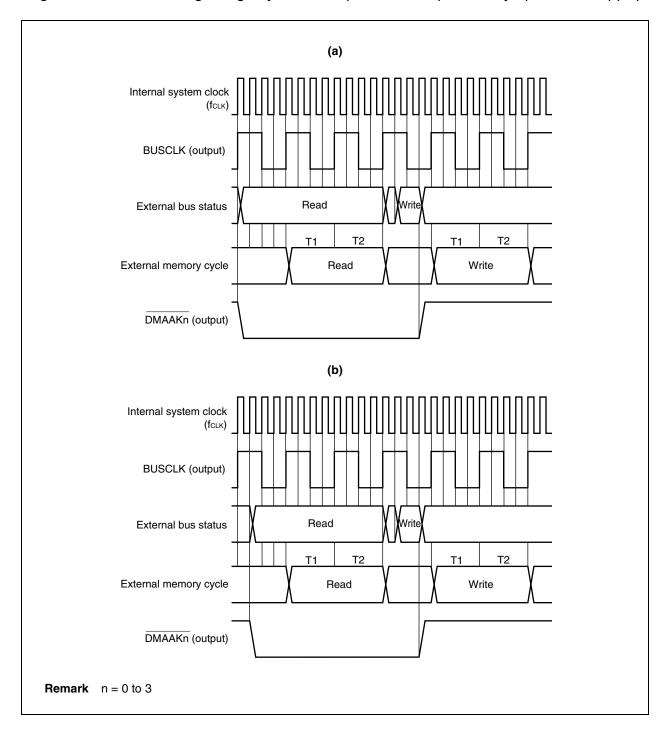

## Figure 6-15. Outline of Timing During 2-Cycle Transfer (SRAM $\rightarrow$ SRAM): Divided by 2 (0 SRAM Waits)

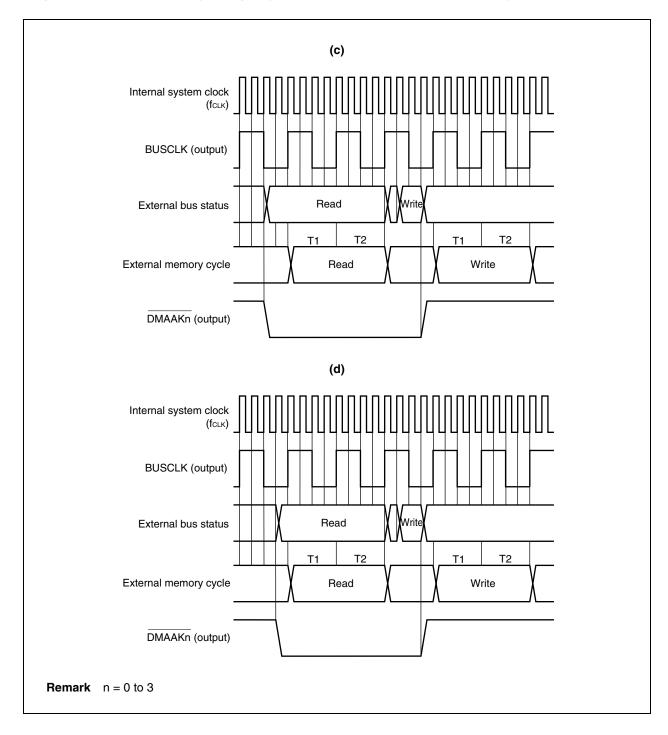

## Figure 6-17. Outline of Timing During 2-Cycle Transfer (SRAM $\rightarrow$ SRAM): Divided by 4 (0 SRAM Waits) (2/2)

## 6.5.2 Flyby transfer

Since data is transferred in 1 cycle during a flyby transfer, a memory address is always output irrespective whether it is a source address or a destination address, and read/write signals of the memory and peripheral I/O become active at the same time. Therefore, the external I/O is selected by the DMAAK0 to DMAAK3 signals.

To perform a normal access to the external I/O by means other than DMA transfer, externally AND the  $\overline{CSm}$  and  $\overline{DMAAKx}$  signals (m = 0 to 7, x = 0 to 3), and connect the resultant signal to the chip select signal of the external I/O. A circuit example of a normal access, other than DMA transfer, to external I/O is shown below.

## 6.6.1 Transfer type and transfer object

Table 6-1 lists the relationships between transfer type and transfer object. The mark " $\sqrt{}$ " means "transfer possible", and the mark " $\times$ " means "transfer impossible".

Table 6-5. Relationship Between Transfer Type and Transfer Object

- Notes 1. If the transfer object is the on-chip peripheral I/O, only the single transfer mode can be used.
  - 2. Transfer can also be executed between a little-endian area and a big-endian area.
  - When the internal instruction RAM is in the write mode (IRAMMn bit of IRAMM register = 1), it can be used only as a transfer destination.
- Cautions 1. The operation is not guaranteed for combinations of transfer destination and source marked with "x" in Table 6-5.
  - 2. In the case of flyby transfer, make the data bus width the same for the source and destination.
  - 3. Addresses between 3FFF000H and 3FFFFFH cannot be specified for the source and destination address of DMA transfer. Be sure to specify an address between FFFF000H and FFFFFFFH.
  - 4. Do not use DMA transfer to set on-chip peripheral I/O registers and to read the set values.
- **Remarks 1.** During 2-cycle DMA transfer, if the data bus width of the transfer source and that of the transfer destination are different, the operation becomes as follows.

If DMA transfer is executed to transfer data of an on-chip peripheral I/O register (as a transfer source or destination), be sure to specify the same transfer size as the register size. For example, to execute DMA transfer of an 8-bit register, be sure to specify byte (8-bit) transfer.

<32-bit transfer>

• Transfer from a 32-bit bus to a 16-bit bus

A read cycle (32 bits) is generated and then a write cycle (16 bits) is generated twice consecutively.

Transfer from a 32-bit bus to an 8-bit bus

A read cycle (32 bits) is generated and then a write cycle (8 bits) is generated 4 times consecutively.

Transfer from a 16-bit bus to an 8-bit bus

A read cycle (16 bits) is generated twice consecutively and then a write cycle (8 bits) is generated 4 times consecutively.

Transfer from a 16-bit bus to a 32-bit bus

A read cycle (16 bits) is generated twice consecutively and then a write cycle (32 bits) is generated. For how to write data to the transfer destination, see **Remark 2** below.

Transfer from an 8-bit bus to a 32-bit bus

A read cycle (8 bits) is generated 4 times consecutively and then a write cycle (32 bits) is generated. For how to write data to the transfer destination, see **Remark 2** below.

Transfer from an 8-bit bus to a 16-bit bus

A read cycle (8 bits) is generated 4 times consecutively and then a write cycle (16 bits) is generated twice consecutively. For how to write data to the transfer destination, see **Remark 2** below.

- <16-bit transfer>
- Transfer from a 32-bit bus to a 16-bit bus

A read cycle (the higher 16 bits are high impedance) is generated and then a write cycle (16 bits) is generated.

- Transfer from a 32-bit bus to an 8-bit bus
   A read cycle (the higher 16 bits are high impedance) is generated and then a write cycle (8 bits) is generated twice consecutively.
- Transfer from a 16-bit bus to an 8-bit bus
   A read cycle (16 bits) is generated and then a write cycle (8 bits) is generated twice consecutively.
- Transfer from a 16-bit bus to a 32-bit bus

A read cycle (16 bits) is generated and then a write cycle (the higher 16 bits are high impedance) is generated. For how to write data to the transfer destination, see **Remark 2** below.

• Transfer from an 8-bit bus to a 32-bit bus

A read cycle (8 bits) is generated twice consecutively and then a write cycle (the higher 16 bits are high impedance) is generated. For how to write data to the transfer destination, see **Remark 2** below.

Transfer from an 8-bit bus to a 16-bit bus

A read cycle (8 bits) is generated twice consecutively and then a write cycle (16 bits) is generated. For how to write data to the transfer destination, see **Remark 2** below.

## <8-bit transfer>

Transfer from a 32-bit bus to a 16-bit bus

A read cycle (the higher 24 bits are high impedance) is generated and then a write cycle (the higher 8 bits are high impedance) is generated.

• Transfer from a 32-bit bus to an 8-bit bus

A read cycle (the higher 24 bits are high impedance) is generated and then a write cycle (8 bits) is generated.

Transfer from a 16-bit bus to an 8-bit bus

A read cycle (the higher 8 bits are high impedance) is generated and then a write cycle (8 bits) is generated.

Transfer from a 16-bit bus to a 32-bit bus

A read cycle (the higher 8 bits are high impedance) is generated and then a write cycle (the higher 24 bits are high impedance) is generated. For how to write data to the transfer destination, see **Remark 2** below.

• Transfer from an 8-bit bus to a 32-bit bus

A read cycle (8 bits) is generated and then a write cycle (the higher 24 bits are high impedance) is generated. For how to write data to the transfer destination, see **Remark 2** below.

- Transfer from an 8-bit bus to a 16-bit bus
   A read cycle (8 bits) is generated and then a write cycle (the higher 8 bits are high impedance) is generated. For how to write data to the transfer destination, see Remark 2 below.
- **Remarks 2.** Under the following conditions, data is written to the lower byte and then the higher byte of the transfer destination in the little-endian mode, and to the higher byte and lower byte of the destination in the big-endian mode.
  - Transfer from a 16-bit bus to a 32-bit bus
  - Transfer from an 8-bit bus to a 32-bit bus
  - Transfer from an 8-bit bus to a 16-bit bus
  - 3. Transfer between the little-endian area and the big-endian area is possible.

### 6.6.2 External bus cycles during DMA transfer

The external bus cycles during DMA transfer are shown below.

Transfer Type	Transfer Object	External Bus Cycle				
2-cycle transfer	On-chip peripheral I/O, internal data RAM, internal instruction RAM	None	_			
	External I/O	Yes	SRAM cycle			
	External memory	Yes	Memory access cycle set by the BCT register			
Flyby transfer	Between external memory and external I/O	Yes	DMA flyby transfer cycle accessing memory that is set as external memory by the BCT register			

### Table 6-6. External Bus Cycles During DMA Transfer

# 6.7 DMA Channel Priorities

The DMA channel priorities are fixed as follows.

DMA channel 0 > DMA channel 1 > DMA channel 2 > DMA channel 3

In the block transfer mode, the channel used for transfer is never switched.

In the single-step transfer mode, if a higher priority DMA transfer request is issued while the bus is released, the higher priority DMA transfer request is acknowledged.

Caution If DMA is started by inputting the same signal to more than one DMARQn pin (n = 0 to 3), a DMA channel with a lower priority may be acknowledged before a DMA channel with a higher priority.

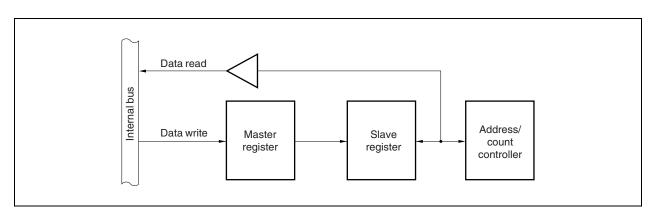

### 6.8 Next Address Setting Function

The DMA source address registers (DSAnH, DSAnL), DMA destination address registers (DDAnH, DDAnL), and DMA transfer count register (DBCn) are buffer registers with a 2-stage FIFO configuration (n = 0 to 3).

When the terminal count is issued, these registers are automatically rewritten with the value that was set immediately before.

Therefore, during DMA transfer, transfer is automatically started when a new DMA transfer setting is made for these registers and the Enn bit of the DCHCn register, and MLEn bit is set to 1 (however, the DMA transfer end interrupt may be issued even if DMA transfer is automatically started).

Figure 6-20 shows the configuration of the buffer register.

The actual DMA transfer is executed in accordance with the contents of the slave register.

The set values that are reflected in the master register and slave register differ as follows, depending on the timing (period) of setting the registers.

#### (1) Period from system reset to the beginning of the first DMA transfer

The set value is reflected in both the master register and slave register.

#### (2) During DMA transfer (period from the beginning to the end of DMA transfer)

The set value is reflected only in the master register and not in the slave register (the slave register holds the set value for the next DMA transfer).

However, the contents of the master register are automatically overwritten to the slave register after completion of DMA transfer. If the value of each register is read during this period, the value of the slave register is read.

### (3) Period from the end of DMA transfer to the beginning of the next DMA transfer

The set value is reflected in both the master register and slave register.

**Remark** "The end of DMA transfer" means either of the following.

- Completion of DMA transfer (terminal count)
- Forced termination of DMA transfer (setting the INITn bit of the DMA channel control register (DCHCn) to 1)

If the setting of a new DMA transfer is made using the DSAnH, DSAnL, DDAnL, and DBCn registers during DMA transfer, the values of the registers are automatically updated after completion of transfer<sup>Note</sup>.

**Note** Before setting a new DMA transfer, confirm the start of the preceding DMA transfer. If the setting of the new DMA transfer is made before the start of the preceding DMA transfer, the new set value is overwritten to both the master register and slave register, and DMA transfer according to the preceding set value cannot be executed.

## 6.9 DMA Transfer Start Factors

There are 4 types of DMA transfer start factors, as shown below.

\*

\*

Cautions 1. Do not use two or more start factors ((1) to (4)) in combination for the same channel (if two or more start factors are generated at the same time, only one of them is valid, but the valid start factor cannot be identified).

The operation is not guaranteed if two or more start factors are used in combination.

2. If DMA transfer is started via software and if the software does not correctly detect whether the expected DMA transfer operation has been completed through manipulation (setting to 1) of the STGn bit of the DCHCn register, it cannot be guaranteed whether the next (second) manipulation of the STGn bit corresponds to the start of "the next DMA transfer expected by software" (n = 0 to 3).

For example, suppose single transfer is started by manipulating the STGn bit. Even if the STGn bit is manipulated next (the second time) without checking by software whether the single transfer has actually been executed, the next (second) DMA transfer is not always executed. This is because the STGn bit may be manipulated the second time before the first DMA transfer is started or completed because, for example, DMA transfer with a higher priority had already been started when the STGn bit was manipulated for the first time.

It is therefore necessary to manipulate the STGn bit next time (the second time) after checking whether DMA transfer started by the first manipulation of the STGn bit has been completed.

Completion of DMA transfer can be checked in the following ways.

- Detecting the acknowledge signal (DMAAKn) or terminal count signal (TCn) by using a peripheral port or interrupt
- Checking the contents of the DBCn register

# (1) Request from an external pin (DMARQn)

Requests from the DMARQn pin are sampled each time the BUSCLK signal rises (n = 0 to 3). Hold the request from  $\overline{DMARQn}$  pin until the corresponding  $\overline{DMAAKn}$  signal becomes active. If a state whereby the Enn bit of the DCHCn register = 1 and the TCn bit = 0 is set, the  $\overline{DMARQn}$  signal becomes valid. If the  $\overline{DMARQn}$  signal set by the DTFRn register becomes active in this status, DMA transfer starts.

## (2) Request from software

If the STGn, Enn, and TCn bits of the DCHCn register are set as follows, DMA transfer starts (n = 0 to 3).

- STGn bit = 1
- Enn bit = 1
- TCn bit = 0

## (3) Request from on-chip peripheral I/O

If, when the Enn and TCn bits of the DCHCn register are set as shown below, an interrupt request is issued from the on-chip peripheral I/O that is set in the DTFRn register, DMA transfer starts (n = 0 to 3).

- Enn bit = 1
- TCn bit = 0

## (4) Request by USB (enabled only in single transfer mode)

If a request is generated from the USB set to the DTFRn register when the Enn and TCn bits of the DCHCn register are set as follows, DMA transfer starts (n = 0 to 3).

- Enn bit = 1
- TCn bit = 0
- **Remark** Since the DMARQn signal is level-sampled and not edge-detected, to enable edge detection of a DMA request, set an external interrupt request for the DMA start trigger instead of using the DMARQn signal (n = 0 to 3).

## 6.10 Terminal Count Output upon DMA Transfer End

The terminal count signal ( $\overline{TCn}$ ) becomes active for one clock of BUSCLK during the last DMA transfer cycle (n = 3 to 0).

The  $\overline{\text{TCn}}$  signal becomes active in the clock following the clock in which the  $\overline{\text{BCYST}}$  signal becomes active during the last DMA transfer cycle.

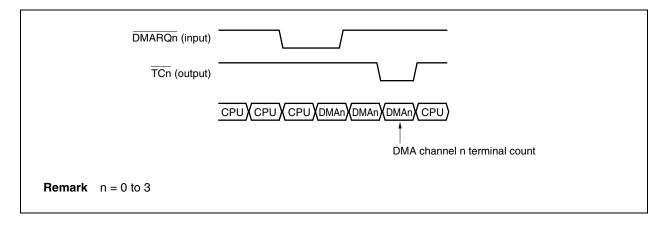

Figure 6-26. Terminal Count Signal (TCn) Timing Example (1)

The TCn signal becomes active for one clock at the beginning of the write cycle of the last DMA transfer when 2-cycle transfer is executed.

When flyby transfer is executed, the  $\overline{TCn}$  signal becomes active for one clock at the beginning of the last DMA transfer cycle.

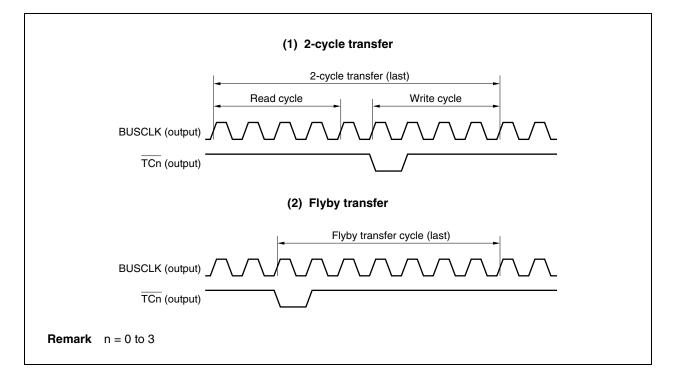

Figure 6-27. Terminal Count Signal (TCn) Timing Example (2)

# 6.11 Forcible Interruption

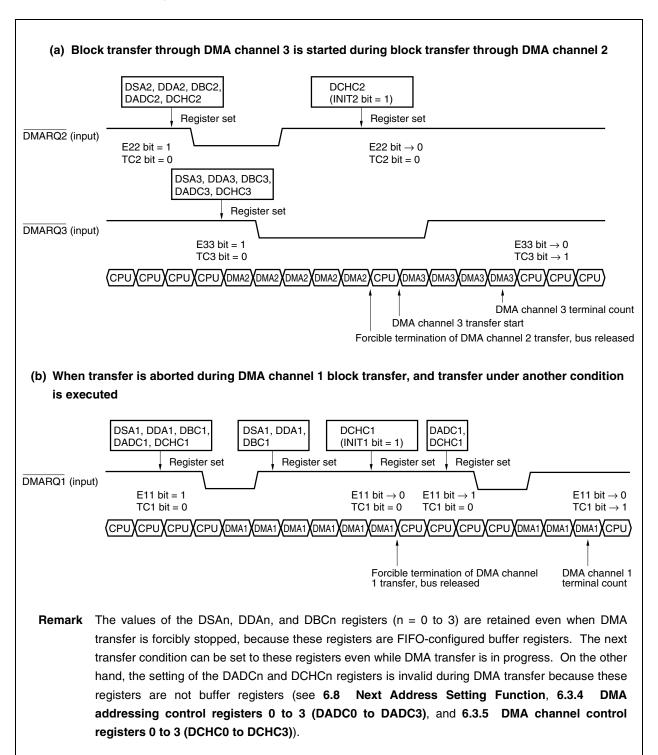

DMA transfer can be forcibly interrupted by NMI input during DMA transfer.

At such a time, the DMAC resets the Enn bit of the DCHCn register of all channels to 0 and the DMA transfer disabled state is entered. An NMI request can then be acknowledged after the DMA transfer that was being executed when the NMI was input is complete (n = 0 to 3).

# 6.12 Forcible Termination

DMA transfer can be forcibly terminated by the INITn bit of the DCHCn register, in addition to the forcible interruption operation by means of NMI input (n = 0 to 3).

An example of forcible termination by the INITn bit of the DCHCn register is illustrated below (n = 0 to 3).

# ★ 6.13 Times Related to DMA Transfer

The overhead before and after DMA transfer and minimum execution clock for DMA transfer are shown below. In the case of external memory access, the time depends on the type of external memory connected.

Table 6-7.	Number of Minimum	Execution	<b>Clocks in</b>	DMA Cycle
------------	-------------------	-----------	------------------	-----------

	DMA Cycle	Number of Minimum Execution Clocks
<1> Time to respond to	DMA request	4 clocks <sup>Note 1</sup>
<2> Memory access	External memory access	Differs depending on the memory connected
	Internal data RAM or internal instruction RAM (read mode) access	2 clocks <sup>Note 2</sup>

Notes 1. If an external interrupt (INTPn) is specified as a factor of starting DMA transfer, noise elimination time is added (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, or L1).

2. Two clocks are required for the DMA cycle.

The minimum execution clock in the DMA cycle in each transfer mode is as follows.

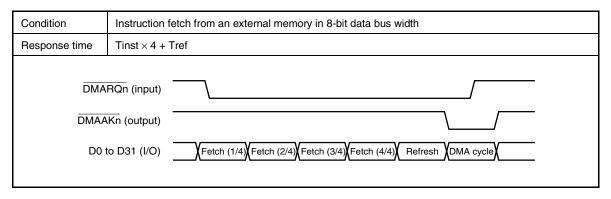

- Single transfer: DMA response time (<1>) + Transfer source memory access (<2>) + 2<sup>Note</sup> + Transfer destination memory access (<2>)
- Block transfer: DMA response time (<1>) + (Transfer source memory access (<2>) + 2<sup>Note</sup> + Transfer destination memory access (<2>)) × Number of transfers

Note Two clocks are always inserted between the read cycle and write cycle of DMA transfer.

## 6.14 Maximum Response Time for DMA Transfer Request

The response time for a DMA transfer request becomes the longest under the following conditions (in the SDRAM refresh cycle enabled state). However, the case when a higher priority DMA transfer is generated is excluded.

## (1) Condition 1

**Remark** n = 0 to 3

# (2) Condition 2

Condition	Word data access with an external memory in 8-bit data bus width
Response time	Tdata $\times$ 4 + Tref
DMAA	RQn (input)         Kn (output)         to D31 (I/O)         \Data (1/4)         Data (2/4)         Data (3/4)         Data (4/4)         Refresh         DMA cycle

### **Remark** n = 0 to 3

# (3) Condition 3

Condition	Instruction fetch from an external memory in 8-bit data bus width Execution of a bit manipulation instruction (SET1, CLR1, or NOT1)
Response time	Tinst $\times$ 4 + Tdata $\times$ 2 + Tref
DMARQn (inpu DMAAKn (output D0 to D31 (I/C	

Remarks 1. Tinst: Number of clocks per bus cycle during instruction fetch Tdata: Number of clocks per bus cycle during data access

Tref: Number of clocks per refresh cycle

**2.** n = 0 to 3

## 6.15 Cautions

## (1) Memory boundary

The transfer operation is not guaranteed if the source or the destination address exceeds the area of DMA objects (external memory, internal data RAM, internal instruction RAM, or peripheral I/O) during DMA transfer.

### (2) Transfer of misaligned data

DMA transfer of 32-/16-bit bus width misaligned data is not supported. If the source or the destination address is set to an odd address, the LSB of the address is forcibly handled as "0".

## ★ (3) Bus arbitration for CPU

When DMA transfer is executed to transfer data to/from an external device, the CPU can access internal data RAM and internal instruction RAM<sup>Note</sup> not being used for DMA transfer.

Because the DMA controller has a priority higher than the CPU acquiring bus mastership, a CPU access that takes place during DMA transfer is kept waiting until the preceding DMA transfer is completed and the bus is released to the CPU. If DMA transfer is executed between the external memory and on-chip peripheral I/O, however, the CPU can access the internal data RAM and internal instruction RAM<sup>Note</sup>.

**Note** When the IRAMM bit of the IRAMM register = 0 (n = 0, 1)

## (4) Holding DMARQn signal

Be sure to keep the  $\overline{DMARQn}$  signal active until the  $\overline{DMAAKn}$  signal becomes active (n = 0 to 3).

## (5) DMAAKn signal output

When the transfer object is internal data RAM, the DMAAKn signal is not output during a DMA cycle for internal data RAM (for example, if 2-cycle transfer is performed from internal data RAM to an external memory, the DMAAKn signal is output only during a DMA write cycle for the external memory).

If the transfer object is the on-chip peripheral I/O or internal instruction RAM, the DMAAKn signal is output even in the DMA cycle executed on the on-chip peripheral I/O or internal instruction RAM.

### (6) DMA start factors

Do not start two or more DMA channels with the same factor. If two or more DMA channels are started with the same factor, the DMA channel with the lower priority may be accepted before the DMA channel with the higher priority.

# (7) Read values of DSAn and DDAn registers

If the values of the DSAn and DDAn registers are read during DMA transfer, the values in the middle of being updated may be read (n = 0 to 3).

For example, if the DSAnH register and the DSAnL register are read in that order when the value of the DMA transfer source address (DSAn register) is "0000FFFFH" and the counting direction is incremental (when the SADn1 and SADn0 bits of the DADCn register = 00), the value of the DSAnL register differs as follows depending on whether DMA transfer is executed immediately after the DSAnH register has been read.

### (a) If DMA transfer does not occur while the DSAn register is being read

- <1> Reading DSAnH register: DSAnH = 0000H
- <2> Reading DSAnL register: DSAnL = FFFFH

### (b) If DMA transfer occurs while the DSAn register is being read

- <1> Reading DSAnH register: DSAnH = 0000H
- <2> Occurrence of DMA transfer
- <3> Incrementing DSAn register : DSAn = 00010000H
- <4> Reading DSAnL register: DSAnL = 0000H

## 6.15.1 Interrupt factors

DMA transfer is interrupted if the following factors are issued.

- Bus hold
- Refresh cycle

If the factor that is interrupting DMA transfer disappears, DMA transfer promptly restarts.

# 6.16 DMA Transfer End

When DMA transfer ends and the TCn bit of the DCHCn register is set to 1, a DMA transfer end interrupt (INTDMAn) is issued to the interrupt controller (INTC) (n = 0 to 3).

# CHAPTER 7 INTERRUPT/EXCEPTION PROCESSING FUNCTION

The V850E/ME2 is provided with a dedicated interrupt controller (INTC) for interrupt servicing and can process a total of 91 interrupt requests.

An interrupt is an event that occurs independently of program execution, and an exception is an event whose occurrence is dependent on program execution.

The V850E/ME2 can process interrupt requests from the on-chip peripheral hardware and external sources. Moreover, exception processing can be started by the TRAP instruction (software exception) or by generation of an exception event (i.e. fetching of an illegal opcode) (exception trap).

# 7.1 Features

O Interrupts

- Non-maskable interrupts: 1 source
- Maskable interrupts: 90 sources
- 8 levels of programmable priorities (maskable interrupts)
- Multiple interrupt control according to priority
- Masks can be specified for each maskable interrupt request.
- Noise elimination<sup>Note</sup>, edge detection, and valid edge specification for external interrupt request signals.

Note For details of the noise eliminator, see 14.6 Noise Eliminator.

#### O Exceptions

- Software exceptions: 32 sources
- Exception traps: 2 sources (illegal opcode exception and debug trap)

Interrupt/exception sources are listed in Table 7-1.

**Remarks 1.** Default Priority: The priority order when two or more maskable interrupt requests occur at the same time. The highest priority is 0.

Restored PC: The value of the PC saved to EIPC or FEPC when interrupt/exception processing is started. However, the value of the PC saved when an interrupt is acknowledged during divide instruction (DIV, DIVH, DIVU, DIVHU) execution is the value of the PC of the current instruction (DIV, DIVH, DIVU, DIVHU).

nextPC: The PC value that starts the processing following interrupt/exception processing.

 The execution address of the illegal instruction when an illegal opcode exception occurs is calculated by (Restored PC – 4).

### 7.2 Non-Maskable Interrupts

A non-maskable interrupt request is acknowledged unconditionally, even when interrupts are in the interrupt disabled (DI) status. An NMI is not subject to priority control and takes precedence over all the other interrupts.

A non-maskable interrupt request is input from the NMI pin. When the valid edge specified by bit 0 (NMIR0) of external interrupt rising edge specification register 2 (INTR2) or bit 0 (NMIF0) of external interrupt falling edge specification register 2 (INTF2) is detected at the NMI pin, the interrupt occurs.

While the service program of the non-maskable interrupt is being executed (PSW.NP = 1), the acknowledgment of another non-maskable interrupt request is held pending. The pending NMI is acknowledged after the original service program of the non-maskable interrupt under execution has been terminated (by the RETI instruction). Note that if two or more NMI requests are input during the execution of the service program for an NMI, the number of NMIs that will be acknowledged after PSW.NP is cleared to 0 is only one.

Remark PSW.NP: The NP bit of the PSW register.

## 7.2.1 Operation

If a non-maskable interrupt is generated, the CPU performs the following processing, and transfers control to the handler routine:

- <1> Saves the restored PC to FEPC.
- <2> Saves the current PSW to FEPSW.
- <3> Writes exception code 0010H to the higher halfword (FECC) of ECR.
- <4> Sets the NP and ID bits of the PSW and clears the EP bit.
- <5> Sets the handler address (00000010H) corresponding to the non-maskable interrupt to the PC, and transfers control.

The servicing configuration of a non-maskable interrupt is shown in Figure 7-1.

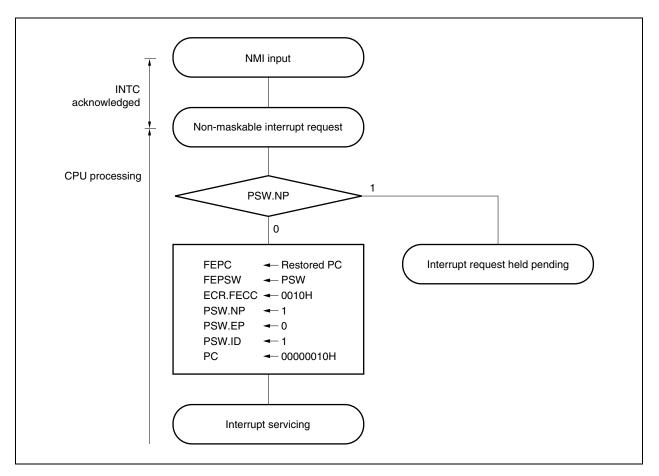

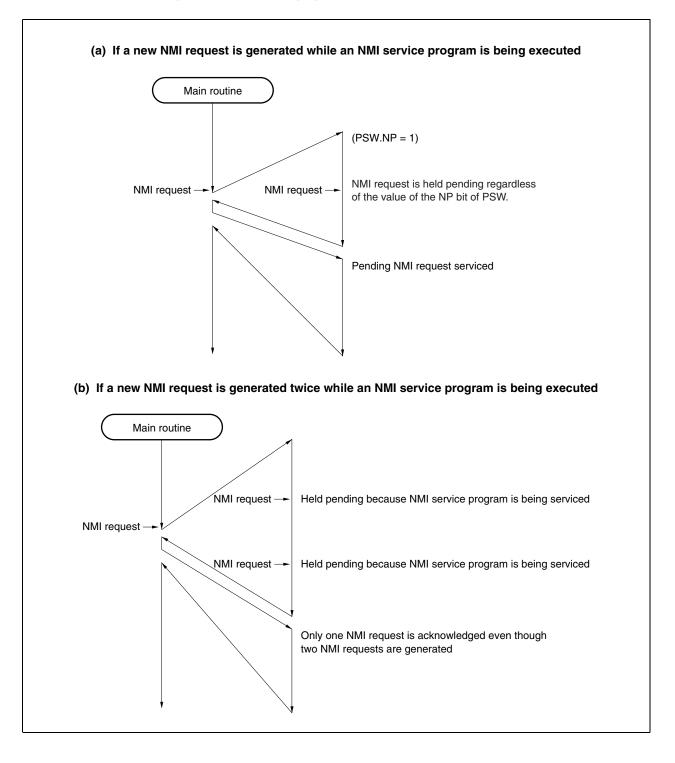

Figure 7-1. Servicing Configuration of Non-Maskable Interrupt

### Figure 7-2. Acknowledging Non-Maskable Interrupt Request

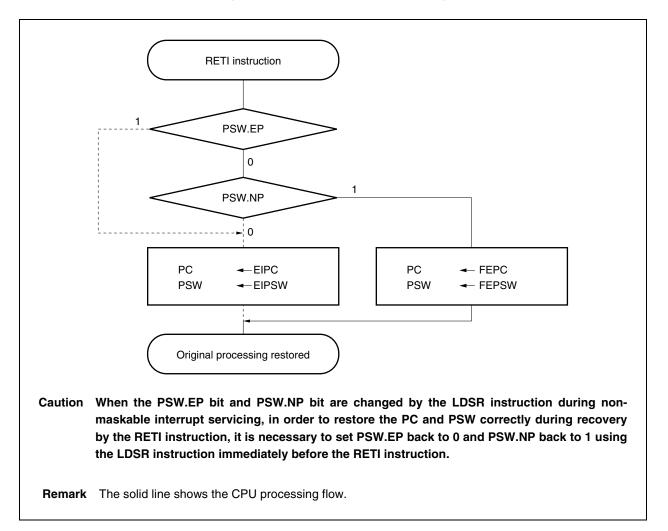

## 7.2.2 Restore

Execution is restored from the non-maskable interrupt servicing by the RETI instruction.

When the RETI instruction is executed, the CPU performs the following processing, and transfers control to the address of the restored PC.

- <1> Restores the values of the PC and the PSW from FEPC and FEPSW, respectively, because the EP bit of the PSW is 0 and the NP bit of the PSW is 1.
- <2> Transfers control back to the address of the restored PC and PSW.

Figure 7-3 illustrates how the RETI instruction is processed.

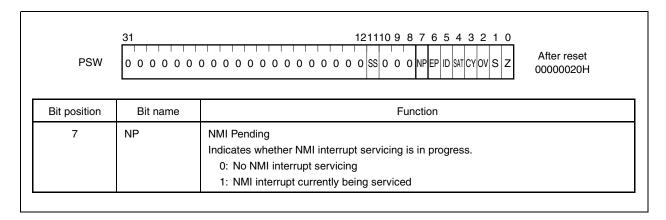

## 7.2.3 Non-maskable interrupt status flag (NP)

The NP flag is a status flag that indicates that non-maskable interrupt (NMI) servicing is under execution.

This flag is set when an NMI interrupt has been acknowledged, and masks all interrupt requests and exceptions to prohibit multiple interrupts from being acknowledged.

## 7.2.4 Edge detection function

(1) External interrupt rising edge specification register 2 (INTR2), external interrupt falling edge specification register 2 (INTF2)

These registers are used to specify the valid edge of the non-maskable interrupt (NMI). The NMIR0 bit of the INTR2 register and NMIF0 bit of the INTF2 register specify the rising edge, falling edge, or both the rising and falling edges of the NMI as the valid edge.

These registers can be read or written in 8-bit or 1-bit units.

# 7.3 Maskable Interrupts

Maskable interrupt requests can be masked by interrupt control registers. The V850E/ME2 has 90 maskable interrupt sources.

If two or more maskable interrupt requests are generated at the same time, they are acknowledged according to the default priority. In addition to the default priority, eight levels of priorities can be specified by using the interrupt control registers (programmable priority control).

When an interrupt request has been acknowledged, the acknowledgment of other maskable interrupt requests is disabled and the interrupt disabled (DI) status is set.

When the EI instruction is executed in an interrupt service routine, the interrupt enabled (EI) status is set, which enables servicing of interrupts having a higher priority than the interrupt request in progress (specified by the interrupt control register). Note that only interrupts with a higher priority will have this capability; interrupts with the same priority level cannot be nested.

However, if multiple interrupts are executed, the following processing is necessary.

- <1> Save EIPC and EIPSW in memory or a general-purpose register before executing the EI instruction.
- <2> Execute the DI instruction before executing the RETI instruction, then reset EIPC and EIPSW with the values saved in <1>.

#### 7.3.1 Operation

If a maskable interrupt occurs by INT input, the CPU performs the following processing, and transfers control to a handler routine:

- <1> Saves the restored PC to EIPC.
- <2> Saves the current PSW to EIPSW.
- <3> Writes an exception code to the lower halfword of ECR (EICC).
- <4> Sets the ID bit of the PSW and clears the EP bit.
- <5> Sets the handler address corresponding to each interrupt to the PC, and transfers control.

The servicing configuration of a maskable interrupt is shown in Figure 7-4.

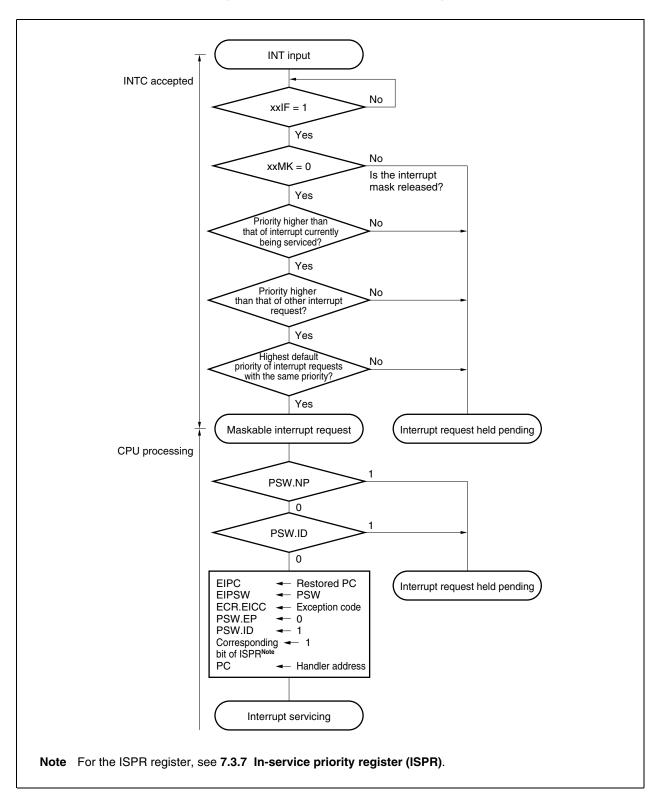

Figure 7-4. Maskable Interrupt Servicing

The INT input masked by the interrupt controllers and the INT input that occurs while another interrupt is being serviced (when PSW.NP = 1 or PSW.ID = 1) are held pending internally by the interrupt controller. In such case, if the interrupts are unmasked, or when PSW.NP = 0 and PSW.ID = 0 as set by the RETI and LDSR instructions, input of the pending INT starts the new maskable interrupt servicing.

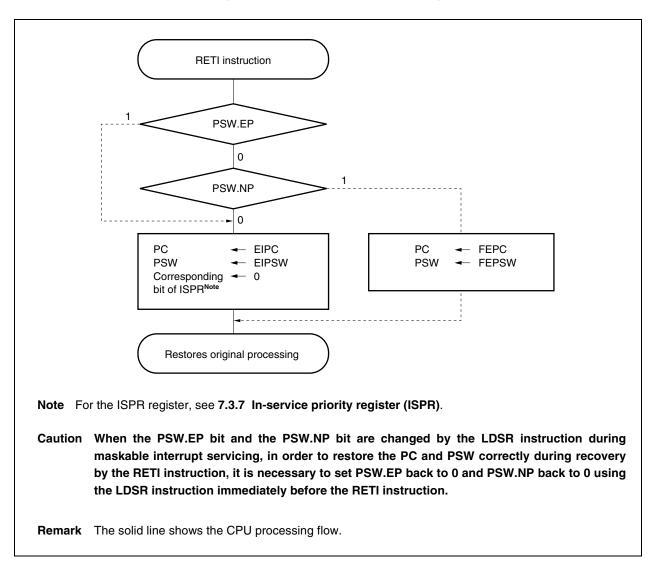

# 7.3.2 Restore

Recovery from maskable interrupt servicing is carried out by the RETI instruction.

When the RETI instruction is executed, the CPU performs the following steps, and transfers control to the address of the restored PC.

- <1> Restores the values of the PC and the PSW from EIPC and EIPSW because the EP bit of the PSW is 0 and the NP bit of the PSW is 0.
- <2> Transfers control to the address of the restored PC and PSW.

Figure 7-5 illustrates the processing of the RETI instruction.

# Figure 7-5. RETI Instruction Processing

#### 7.3.3 Priorities of maskable interrupts

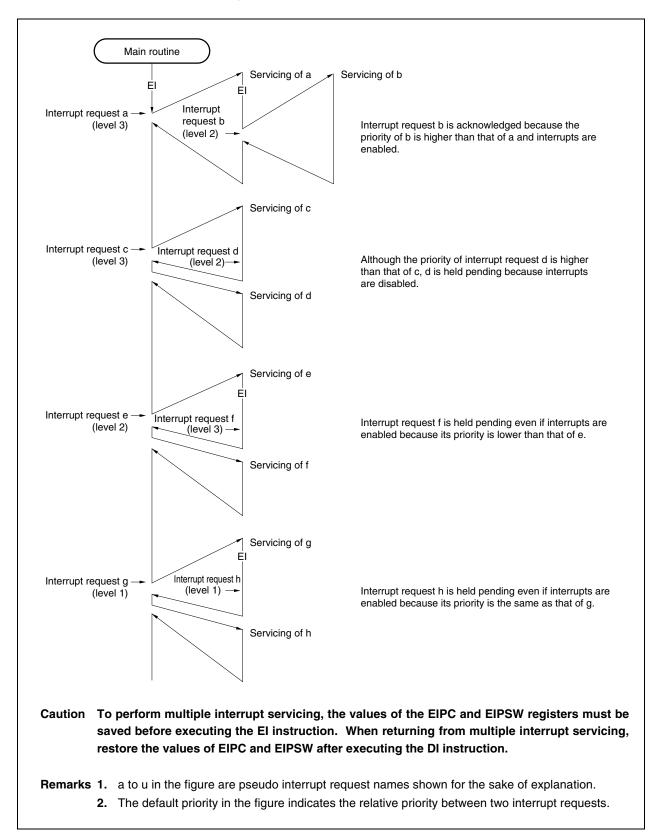

The V850E/ME2 provides multiple interrupt servicing in which an interrupt is acknowledged while another interrupt is being serviced. Multiple interrupts can be controlled by priority levels.

There are two types of priority level control: control based on the default priority levels, and control based on the programmable priority levels that are specified by the interrupt priority level specification bit (xxPRn) of the interrupt control register (xxICn). When two or more interrupts having the same priority level specified by the xxPRn bit are generated at the same time, interrupts are serviced in order depending on the priority level allocated to each interrupt request type (default priority level) beforehand. For more information, see **Table 7-1 Interrupt/Exception Source List**. The programmable priority control customizes interrupt requests into eight levels by setting the priority level specification flag.

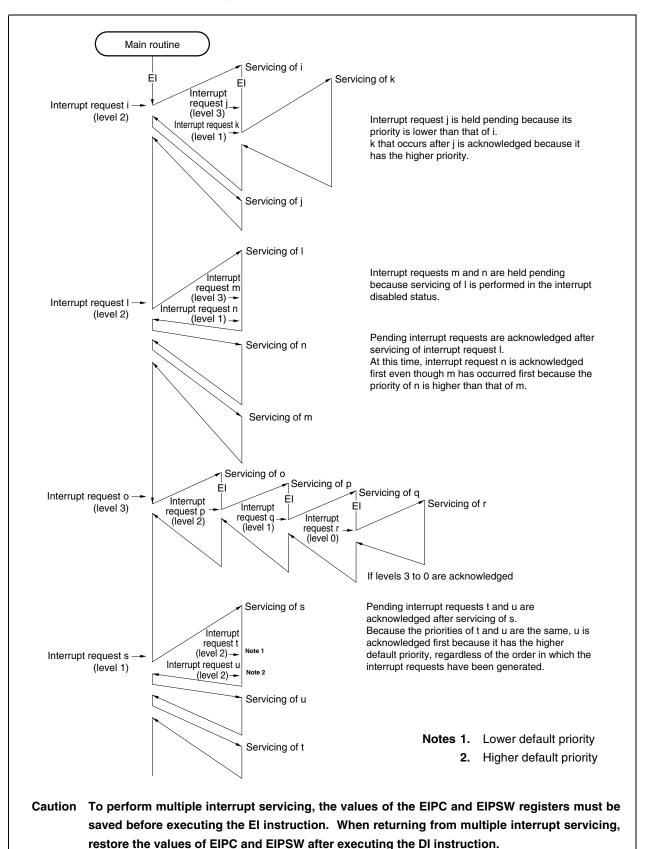

Note that when an interrupt request is acknowledged, the ID flag of PSW is automatically set to 1. Therefore, when multiple interrupts are to be used, clear the ID flag to 0 beforehand (for example, by placing the EI instruction in the interrupt service program) to set the interrupt enable mode.

Remark xx: Identification name of each peripheral unit (see Table 7-2)

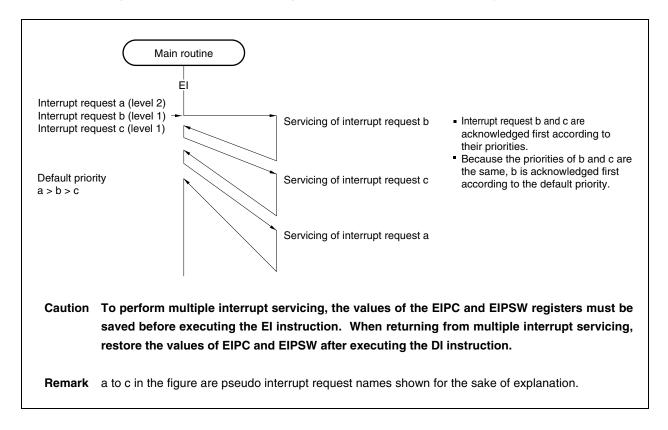

n: Peripheral unit number (see Table 7-2)

#### Figure 7-7. Example of Servicing Interrupt Requests Simultaneously Generated

# 7.3.4 Interrupt control register (xxICn)

An interrupt control register is assigned to each interrupt request (maskable interrupt) and sets the control conditions for each maskable interrupt request.

This register can be read or written in 8-bit or 1-bit units.

# Caution Disable interrupts (DI) to read the xxIFn bit of the xxICn register. If the xxIFn bit is read while interrupts are enabled (EI), the correct value may not be read if there is a conflict between acknowledging an interrupt and reading the bit.

Table 7-2. Addresses and Bits of Interrupt Control Registers (3/3)

#### 7.3.5 Interrupt mask registers 0 to 5 (IMR0 to IMR5)

These registers set the interrupt mask state for the maskable interrupts. The xxMKn bit of the IMR0 to IMR5 registers is equivalent to the xxMKn bit of the xxICn register.

The IMRm register (m = 0 to 5) can be read or written in 16-bit units.

If the higher 8 bits of the IMRm register are used as an IMRmH register and the lower 8 bits as an IMRmL register, these registers can be read or written in 8-bit or 1-bit units.

Bits 15 to 10 of the IMR5 register (bits 7 to 2 of the IMR5H register) are fixed to 1. If these bits are not 1, the operation cannot be guaranteed.

Caution The device file defines the xxMKn bit of the xxICn register as a reserved word. If a bit is manipulated using the name of xxMKn, the contents of the xxICn register, instead of the IMRm register, are rewritten (as a result, the contents of the IMRm register are also rewritten).

#### 7.3.6 NMI reset status register (NRS)

This register holds the valid edge input status of the NMI after the reset signal has been cleared. This register is read-only, in 8-bit or 1-bit units.

- Cautions 1. The NMIRS bit of the NRS register is set to 1 if an NMI occurs after the internal instruction RAM has been set in the read mode (IRAMM0 bit of IRAMM register = 0). In this case, the status of the NMIRS bit does not have to be checked because execution automatically branches to the NMI servicing routine.
  - 2. The mask function of NMI input is valid after the reset signal has been cleared and before the internal instruction RAM is set in the read mode (IRAMM0 bit of IRAMM register = 0).

_	7	6	5	4	3	2	1	0	Address	After reset		
NRS	0	0	0	0	0	0	0	NMIRS	FFFFF80CH	00H		
Bit position Bit name			1				Functio	n				
0				Function Indicates the valid edge input status of NMI. 0: No NMI input 1: NMI input								

With the V850E/ME2, the NMI is masked after the reset signal has been cleared. It is unmasked if the mode of the internal instruction RAM is changed from the write mode (IRAMM0 bit of IRAMM register = 1) to the read mode (IRAMM0 bit of IRAMM register = 0) after the program has been downloaded to internal instruction RAM bank 0. (The NRS register is controlled to prohibit a jump to the interrupt vector before the program is stored in the interrupt vector table.)

If the NMI valid edge is input while the NMI is masked, the NMI input can be recognized by reading the NRS register.

# 7.3.7 In-service priority register (ISPR)

This register holds the priority level of the maskable interrupt currently acknowledged. When an interrupt request is acknowledged, the bit of this register corresponding to the priority level of that interrupt request is set to 1 and remains set while the interrupt is serviced.

When the RETI instruction is executed, the bit corresponding to the interrupt request having the highest priority is automatically reset to 0 by hardware. However, it is not reset to 0 when execution is returned from non-maskable interrupt servicing or exception processing.

This register is read-only, in 8-bit or 1-bit units.

Caution If an interrupt is acknowledged while the ISPR register is being read in the interrupt enabled (EI) status, the value of the ISPR register after the bits of the register have been set to 1 by acknowledging the interrupt may be read. To accurately read the value of the ISPR register before an interrupt is acknowledged, read the register while interrupts are disabled (DI status).

7 to	7 to 0 ISPR7 to ISPR0		0:	Indicates priority of interrupt currently acknowledged 0: Interrupt request with priority n not acknowledged 1: Interrupt request with priority n acknowledged										

#### 7.3.8 Maskable interrupt status flag (ID)

The ID flag is bit 5 of the PSW and controls the maskable interrupt's operating state, and stores control information regarding enabling or disabling of interrupt requests.

PSW	31 0 0 0 0 0 0	121110 9 8 7 6 5 4 3 2 1 0         0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
Bit position	Bit name	Function
5	ID	<ul> <li>Indicates whether maskable interrupt servicing is enabled or disabled.</li> <li>0: Maskable interrupt request acknowledgment enabled</li> <li>1: Maskable interrupt request acknowledgment disabled (pending)</li> <li>This bit is set to 1 by the DI instruction and reset to 0 by the EI instruction. Its value is also modified by the RETI instruction or LDSR instruction when referencing the PSW.</li> <li>Non-maskable interrupt requests and exceptions are acknowledged regardless of this flag. When a maskable interrupt is acknowledged, the ID flag is automatically set to 1 by hardware.</li> <li>The interrupt request generated during the acknowledgment disabled period (ID = 1) is acknowledged when the xxIFn bit of xxICn is set to 1, and the ID flag is reset to 0.</li> </ul>

# 7.3.9 Selecting interrupt trigger mode

The valid edge of the  $\overline{INTPn}$ , INTPCm, TIC0 to TIC3, INTPx, TIUD10, TIUD11, TCUD10, TCUD11, TCLR10, and TCLR11 pins can be selected by program (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, L0, L1, or D0 to D15, m = 00, 01, 10, 11, 20, 21, 30, or 31, x = 100, 101, 110, or 111). A trigger level can also be selected for the  $\overline{INTPn}$  pin. The following valid edges can be selected.

- Rising edge
- Falling edge
- Both rising and falling edges

The INTPn, INTPCm, TIC0 to TIC3, INTPx, TIUD10, TIUD11, TCUD10, TCUD11, TCLR10, and TCLR11 signals detected by the edge are used as interrupt sources, to input a capture trigger, or to input an external count signal to the timers.

The valid edge of these signals is specified by external interrupt rising edge specification registers 1, 2, 5, 6, AL, and DH (INTR1, INTR2, INTR5, INTR6, INTRAL, and INTRDH), external interrupt falling edge specification registers 1, 2, 5, 6, AL, and DH (INTF1, INTF2, INTF5, INTF6, INTFAL, and INTFDH), valid edge select registers C0 to C3 (SESC0 to SESC3), and valid edge select registers 10 and 11 (SESA10 and SESA11). The trigger level is specified by external interrupt rising edge specification registers 1, 2, 5, 6, AL, and DH (INTR1, INTR2, INTR5, INTR6, INTRAL, and INTRDH) and external interrupt falling edge specification registers 1, 2, 5, 6, AL, and DH (INTR1, INTR2, INTR5, INTR6, INTRAL, and INTRDH) and external interrupt falling edge specification registers 1, 2, 5, 6, AL, and DH (INTR1, INTR2, INTR5, INTR6, INTRAL, and INTRDH) and external interrupt falling edge specification registers 1, 2, 5, 6, AL, and DH (INTR1, INTR2, INTR5, INTR6, INTRAL, and INTRDH).

(1) External interrupt rising edge specification register 1 (INTR1), external interrupt falling edge specification register 1 (INTF1)

These registers are used to specify the trigger mode of the external interrupt requests (INTP10 and INTP11) input from external pins. The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTF10 and INTR10 bits: INTP10
- INTF11 and INTR11 bits: INTP11

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge.

Each of these registers can be read or written in 8-bit or 1-bit units.

Caution Before setting the trigger mode of the INTP10 and INTP11 pins, set the PMC1 register. If the PMC1 register is set after the INTR1 and INTF1 registers have been set, an illegal interrupt may occur when the PMC1 register is set.

					1	1	Both risin	g and falling	edges					

- **Notes 1.** The level of the INTP1n pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the P1IFn bit (n = 0, 1). Consequently, even when the CPU acknowledges the interrupt and the P1IFn bit of the interrupt control register (P1ICn) is automatically cleared to 0, the P1IFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the INTP1n pin of the external device inactive in the interrupt servicing routine, and forcibly clear the P1IFn bit to 0.
  - 2. If a level-detected interrupt request (INTP1n) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request (INTP1n) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt (INTP1n) is held pending (n = 0, 1). To not acknowledge the interrupt request of INTP1n, clear the P1IFn bit of the interrupt control register.

(2) External interrupt rising edge specification register 2 (INTR2), external interrupt falling edge specification register 2 (INTF2)

These registers are used to specify the trigger mode of the external interrupt requests (INTP2n) input from external pins and the non-maskable interrupt (NMI) (n = 1 to 5). For the trigger mode of the NMI, see **7.2.4** 

(1) External interrupt rising edge specification register 2 (INTR2), external interrupt falling edge specification register 2 (INTF2).

The correspondence between each bit and the external interrupt request and non-maskable interrupt that are controlled by that bit is as follows.

- INTF21 and INTR21 bits: INTP21
- INTF22 and INTR22 bits: INTP22
- INTF23 and INTR23 bits: INTP23
- INTF24 and INTR24 bits: INTP24
- INTF25 and INTR25 bits: INTP25

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge of the INTP2n pin.

Each of these registers can be read or written in 8-bit or 1-bit units.

Caution Before setting the trigger mode of the INTP2n pin, set the PMC2 register (n = 1 to 5). If the PMC2 register is set after the INTR2 and INTF2 registers have been set, an illegal interrupt may occur when the PMC2 register is set.

To not acknowledge the interrupt request of INTP2n, clear the P2IFn bit of the interrupt control register.
- Remark For the bit 0 (NMIR0) of the INTR2 register and bit 0 (NMIF0) of the INTF2 register, see 7.2.4 (1) External interrupt rising edge specification register 2 (INTR2), external interrupt falling edge specification register 2 (INTF2).

(3) External interrupt rising edge specification register 5 (INTR5), external interrupt falling edge specification register 5 (INTF5)

These registers are used to specify the trigger mode of the external interrupt requests (INTP5n) input from external pins (n = 0 to 2). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTF50 and INTR50 bits: INTP50
- INTF51 and INTR51 bits: INTP51
- INTF52 and INTR52 bits: INTP52

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge.

Each of these registers can be read or written in 8-bit or 1-bit units.

#### Caution Before setting the trigger mode, set the PMC5 register.

If the PMC5 register is set after the INTR5 and INTF5 registers have been set, an illegal interrupt may occur when the PMC5 register is set.

To not acknowledge the interrupt request of INTP5n, clear the P5IFn bit of the interrupt control register.

(4) External interrupt rising edge specification register 6 (INTR6), external interrupt falling edge specification register 6 (INTF6)

These registers are used to specify the trigger mode of the external interrupt requests (INTP6n) input from external pins (n = 5 to 7). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTF65 and INTR65 bits: INTP65
- INTF66 and INTR66 bits: INTP66
- INTF67 and INTR67 bits: INTP67

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge.

Each of these registers can be read or written in 8-bit or 1-bit units.

#### Caution Before setting the trigger mode, set the PMC6 register.

If the PMC6 register is set after the INTR6 and INTF6 registers have been set, an illegal interrupt may occur when the PMC6 register is set.

To not acknowledge the interrupt request of INTP6n, clear the P6IFn bit of the interrupt control register.

(5) External interrupt rising edge specification register AL (INTRAL), external interrupt falling edge specification register AL (INTFAL)

These registers are used to specify the trigger mode of the external interrupt requests (INTPLn) input from external pins (n = 0, 1). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

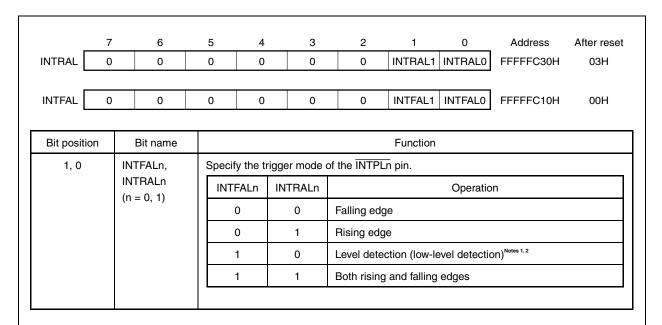

- INTFAL0 and INTRAL0 bits: INTPL0
- INTFAL1 and INTRAL1 bits: INTPL1

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge.

Each of these registers can be read or written in 8-bit or 1-bit units.

# Caution Before setting the trigger mode, set the PMCAL register.

If the PMCAL register is set after the INTRAL and INTFAL registers have been set, an illegal interrupt may occur when the PMCAL register is set.

- **Notes 1.** The level of the INTPLn pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the PLIFn bit (n = 0, 1). Consequently, even when the CPU acknowledges the interrupt and the PLIFn bit of the interrupt control register (PLICn) is automatically cleared to 0, the PLIFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the INTPLn pin of the external device inactive in the interrupt servicing routine, and forcibly clear the PLIFn bit to 0.
  - 2. If a level-detected interrupt request (INTPLn) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request (INTPLn) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt (INTPLn) is held pending (n = 0, 1). To not acknowledge the interrupt request of INTPLn, clear the PLIFn bit of the interrupt control register.

(6) External interrupt rising edge specification register DH (INTRDH), external interrupt falling edge specification register DH (INTFDH)

These registers are used to specify the trigger mode of the external interrupt requests (INTPDn) input from external pins (n = 0 to 15). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTFDH0 and INTRDH0 bits: INTPD0
- INTFDH1 and INTRDH1 bits: INTPD1
- INTFDH2 and INTRDH2 bits: INTPD2
- INTFDH3 and INTRDH3 bits: INTPD3
- INTFDH4 and INTRDH4 bits: INTPD4
- INTFDH5 and INTRDH5 bits: INTPD5
- INTFDH6 and INTRDH6 bits: INTPD6
- INTFDH7 and INTRDH7 bits: INTPD7

- INTFDH8 and INTRDH8 bits: INTPD8
- INTFDH9 and INTRDH9 bits: INTPD9
- INTFDH10 and INTRDH10 bits: INTPD10
- INTFDH11 and INTRDH11 bits: INTPD11
- INTFDH12 and INTRDH12 bits: INTPD12
- INTFDH13 and INTRDH13 bits: INTPD13
- INTFDH14 and INTRDH14 bits: INTPD14
- INTFDH15 and INTRDH15 bits: INTPD15

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge.

The INTRDH and INTFDH registers can be read or written in 16-bit units.

If the higher 8 bits of the INTRDH and INTFDH registers are used as the INTRDHH and INTFDHH registers, and the lower 8 bits as the INTRDHL and INTFDHL registers, these registers can be read or written in 8-bit or 1-bit units.

# Caution Before setting the trigger mode, set the PMCDH register.

If the PMCDH register is set after the INTRDH and INTFDH registers have been set, an illegal interrupt may occur when the PMCDH register is set.

- **Notes 1.** The level of the INTPDn pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the PDIFn bit (n = 0 to 15). Consequently, even when the CPU acknowledges the interrupt and the PDIFn bit of the interrupt control register (PDICn) is automatically cleared to 0, the PDIFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the INTPDn pin of the external device inactive in the interrupt servicing routine, and forcibly clear the PDIFn bit to 0.
  - 2. If a level-detected interrupt request (INTPDn) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request (INTPDn) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt (INTPDn) is held pending (n = 0 to 15). To not acknowledge the interrupt request of INTPDn, clear the PDIFn bit of the interrupt control register.

# (7) Valid edge select registers C0 to C3 (SESC0 to SESC3)

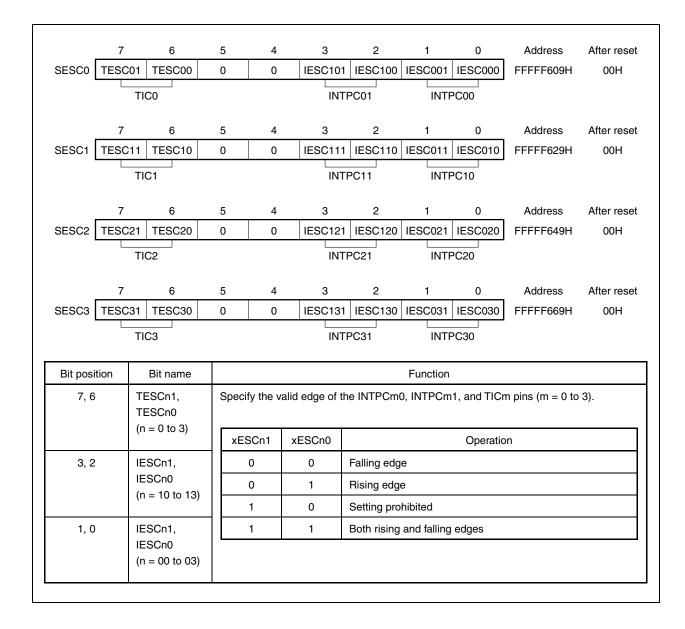

These registers are used to specify the valid edge of the external interrupt requests (INTPC00, INTPC01, INTPC10, INTPC11, INTPC20, INTPC21, INTPC30, INTPC31, or TIC0 to TIC3) input from external pins to TMCn (n = 0 to 3).

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge.

Each of these registers can be read or written in 8-bit units.

Be sure to clear bits 5 and 4 to 0. If they are set to 1, the operation is not guaranteed.

- Cautions 1. Do not change each bit of the SESCn register while the timer is operating (n = 0 to 3). To change a bit, clear the CECn bit of the TMCCn0 register to 0. The operation is not guaranteed if the SESCn register is rewritten during timer operation.
  - 2. Even when the INTPC00/TIC0, INTPC10/TIC1, INTPC20/TIC2, and INTPC30/TIC3 pins are used as INTPC00, INTPC10, INTPC20, and INTPC30, respectively, without using timer C, be sure to set the CAECn and CECn bits of timer mode control registers C00 to C03 (TMCC00 to TMCC30) to 1.
  - 3. Before setting the trigger mode of the INTPC00, INTPC01, INTPC10, INTPC11, INTPC20, INTPC21, INTPC30, INTPC31, and TIC0 to TIC3 pins, set the PMCx register (x = 5 to 7). Then set the CAECn and CECn bits of the TMCCn0 register to 1 (n = 0 to 3). If the PMCx register is set after the SESCn register has been set, an illegal interrupt, incorrect count, or incorrect clear may occur depending on the timing of setting the PMCx register (n = 0 to 3, x = 5 to 7).

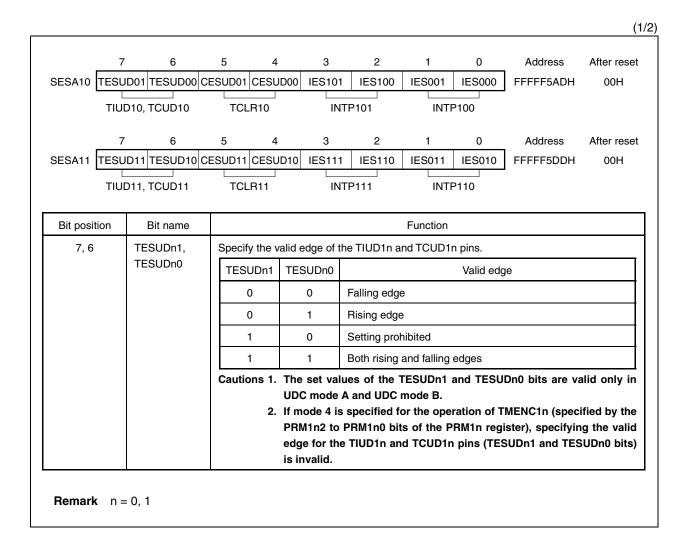

# (8) Valid edge select registers 10, 11 (SESA10, SESA11)

These registers are used to specify the valid edge of the external interrupt requests (TIUD10, TIUD11, TCUD10, TCUD11, TCLR10, or TCLR11) input from external pins and the external capture trigger inputs to timer ENC1 (INTP100, INTP101, INTP110, or INTP111).

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge.

Each of these registers can be read or written in 8-bit or 1-bit units.

- Cautions 1. Changing each bit of the SESA1n register is prohibited while TMENC1n is operating (CE1n1 bit = 1).
  - 2. Before setting the trigger mode of the INTP100, INTP101, INTP110, INTP111, TIUD10, TIUD11, TCUD10, TCUD11, TCLR10, and TCLR11 pins, set the PMCDH register. If the PMCDH register is set after the SESA1n register has been set, an illegal interrupt, incorrect count, or incorrect clear may occur depending on the timing of setting the PMCDH register.

# 7.4 Software Exception

A software exception is generated when the CPU executes the TRAP instruction, and can always be acknowledged.

#### 7.4.1 Operation

If a software exception occurs, the CPU performs the following processing, and transfers control to the handler routine:

- <1> Saves the restored PC to EIPC.
- <2> Saves the current PSW to EIPSW.
- <3> Writes an exception code to the lower 16 bits (EICC) of ECR (interrupt source).
- <4> Sets the EP and ID bits of the PSW.
- <5> Sets the handler address (00000040H or 00000050H) corresponding to the software exception to the PC, and transfers control.

Figure 7-8 illustrates the processing of a software exception.

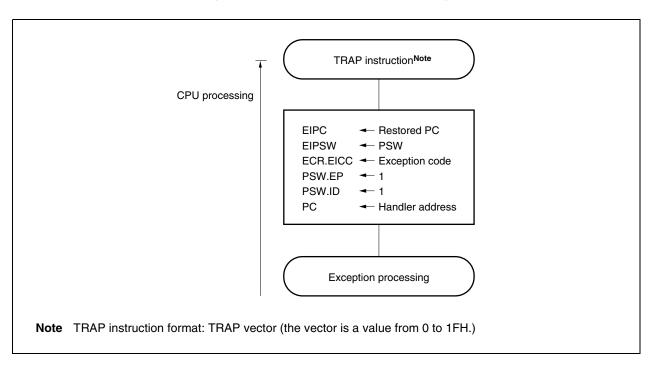

Figure 7-8. Software Exception Processing

The handler address is determined by the TRAP instruction's operand (vector). If the vector is 0 to 0FH, it becomes 00000040H, and if the vector is 10H to 1FH, it becomes 00000050H.

# 7.4.2 Restore

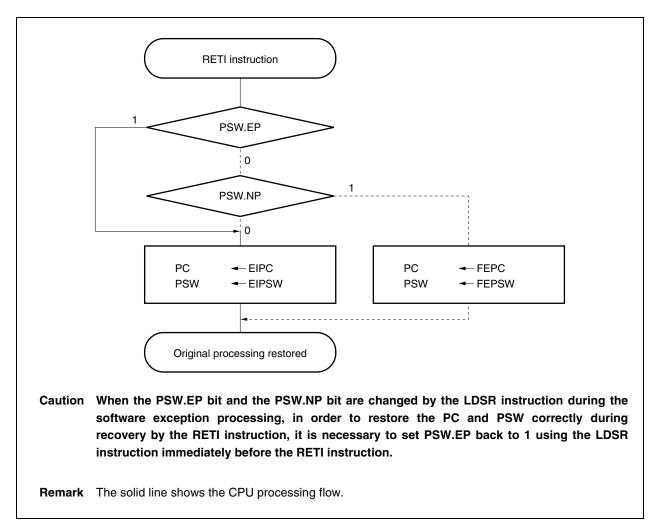

Recovery from software exception processing is carried out by the RETI instruction.

By executing the RETI instruction, the CPU carries out the following processing and shifts control to the restored PC's address.

- <1> Loads the restored PC and PSW from EIPC and EIPSW because the EP bit of the PSW is 1.
- <2> Transfers control to the address of the restored PC and PSW.

Figure 7-9 illustrates the processing of the RETI instruction.

# 7.4.3 Exception status flag (EP)

The EP flag is bit 6 of the PSW, and is a status flag used to indicate that exception processing is in progress. It is set when an exception occurs.

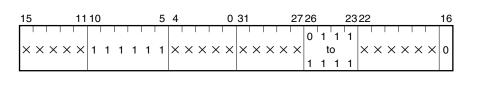

PSW	31 0 0 0 0 0 0 0 0	1211109876543210         0000000000000         000000000000000000000000000000000000
Bit positio	n Bit name	Function
6	EP	Shows that exception processing is in progress. 0: Exception processing not in progress. 1: Exception processing in progress.

# 7.5 Exception Trap

An exception trap is an interrupt that is requested when the illegal execution of an instruction takes place. In the V850E/ME2, an illegal opcode exception (ILGOP: Illegal Opcode Trap) is considered as an exception trap.

#### 7.5.1 Illegal opcode definition

The illegal instruction has an opcode (bits 10 to 5) of 111111B, a sub-opcode (bits 26 to 23) of 0111B to 1111B, and a sub-opcode (bit 16) of 0B. An exception trap is generated when an instruction applicable to this illegal instruction is executed.

×: Arbitrary

# Caution Since it is possible to assign this instruction to an illegal opcode in the future, it is recommended that it not be used.

# (1) Operation

If an exception trap occurs, the CPU performs the following processing, and transfers control to the handler routine:

- <1> Saves the restored PC to DBPC.
- <2> Saves the current PSW to DBPSW.
- <3> Sets the NP, EP, and ID bits of the PSW.
- <4> Sets the handler address (00000060H) corresponding to the exception trap to the PC, and transfers control.

Figure 7-10 illustrates the processing of the exception trap.

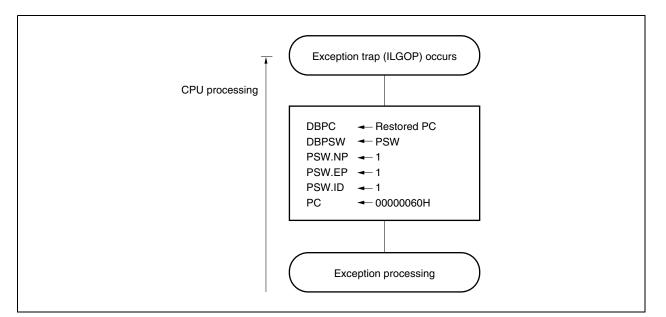

Figure 7-10. Exception Trap Processing

#### (2) Restore

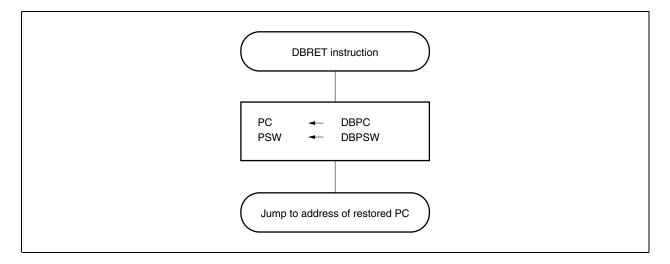

Recovery from an exception trap is carried out by the DBRET instruction. By executing the DBRET instruction, the CPU carries out the following processing and controls the address of the restored PC.

<1> Loads the restored PC and PSW from DBPC and DBPSW.

<2> Transfers control to the address indicated by the restored PC and PSW.

Figure 7-11 illustrates the restore processing from an exception trap.

# 7.5.2 Debug trap

The debug trap is an exception that can be acknowledged every time and is generated by execution of the DBTRAP instruction.

When the debug trap is generated, the CPU performs the following processing.

# (1) Operation

- <1> Saves the restored PC to DBPC.
- <2> Saves the current PSW to DBPSW.
- <3> Sets the NP, EP and ID bits of the PSW.
- <4> Sets the handler address (00000060H) corresponding to the debug trap to the PC and transfers control.

Figure 7-12 illustrates the processing of the debug trap.

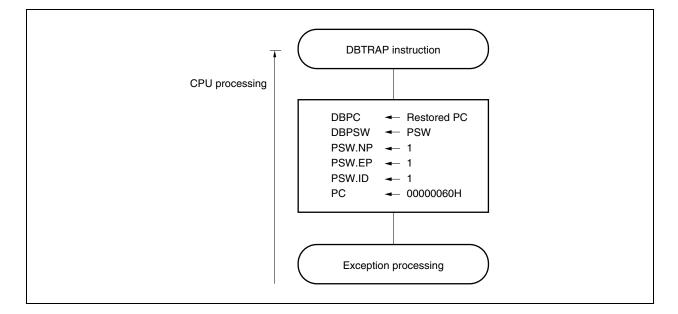

Figure 7-12. Debug Trap Processing

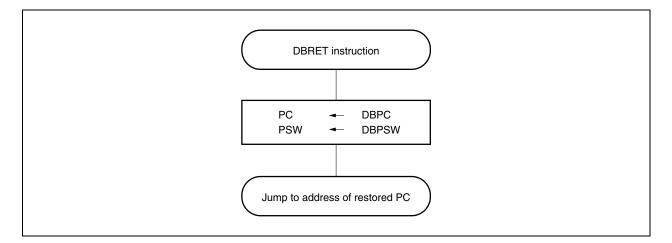

# (2) Restore

Recovery from a debug trap is carried out by the DBRET instruction. By executing the DBRET instruction, the CPU carries out the following processing and controls the address of the restored PC.

<1> Loads the restored PC and PSW from DBPC and DBPSW.

<2> Transfers control to the address indicated by the restored PC and PSW.

Figure 7-13 illustrates the restore processing from a debug trap.

# 7.6 Multiple Interrupt Servicing Control

Multiple interrupt servicing control is a process by which an interrupt request that is currently being serviced can be interrupted during servicing if there is an interrupt request with a higher priority level, and the higher priority interrupt request is acknowledged and serviced first.

If there is an interrupt request with a lower priority level than the interrupt request currently being serviced, that interrupt request is held pending.

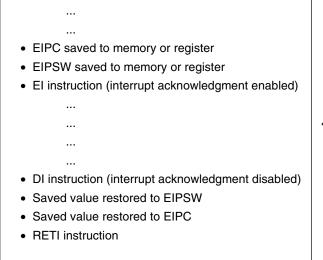

Multiple interrupt servicing control of maskable interrupts is executed when interrupts are enabled (ID = 0). Thus, to execute multiple interrupts, it is necessary to set the interrupt enabled state (ID = 0) even for an interrupt service routine.

If maskable interrupts are enabled or a software exception is generated in a maskable interrupt or software exception service program, it is necessary to save EIPC and EIPSW.

This is accomplished by the following procedure.

#### (1) Acknowledgment of maskable interrupts in service program

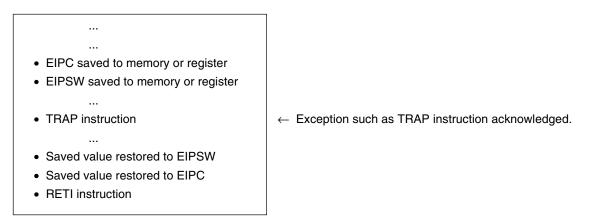

Service program of maskable interrupt or exception

← Maskable interrupt acknowledgment

### (2) Generation of exception in service program

Service program of maskable interrupt or exception

The priority order for multiple interrupt servicing control has 8 levels, from 0 to 7 for each maskable interrupt request (0 is the highest priority), but it can be set as desired via software. The priority order is set using the xxPRn0 to xxPRn2 bits of the interrupt control request register (xxICn), provided for each maskable interrupt request. After system reset, an interrupt request is masked by the xxMKn bit and the priority order is set to level 7 by the xxPRn0 to xxPRn2 bits.

The priority order of maskable interrupts is as follows.

(High) Level 0 > Level 1 > Level 2 > Level 3 > Level 4 > Level 5 > Level 6 > Level 7 (Low)

Interrupt servicing that has been suspended as a result of multiple servicing control is resumed after the servicing of the higher priority interrupt has been completed and the RETI instruction has been executed. A pending interrupt request is acknowledged after the current interrupt servicing has been completed and the RETI instruction has been executed.

# Caution In a non-maskable interrupt service routine (time until the RETI instruction is executed), maskable interrupts are suspended and not acknowledged.

Remark xx: Identification name of each peripheral unit (see Table 7-2)

n: Peripheral unit number (see Table 7-2)

# 7.7 Interrupt Latency Time

The V850E/ME2 interrupt latency time (from interrupt request generation to start of interrupt servicing) is described below.

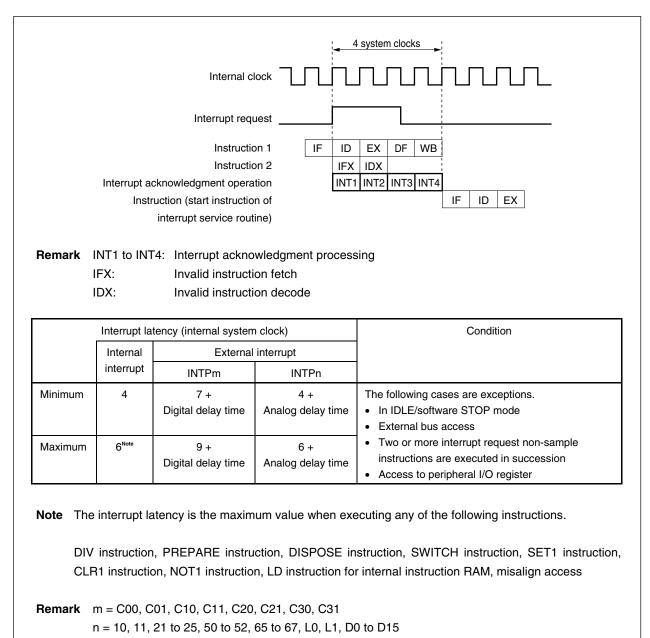

Figure 7-14. Pipeline Operation at Interrupt Request Acknowledgment (Outline)

# 7.8 Periods in Which Interrupts Are Not Acknowledged

An interrupt is acknowledged while an instruction is being executed. However, no interrupt will be acknowledged between an interrupt request non-sample instruction and the next instruction (interrupt is held pending).

The interrupt request non-sample instructions are as follows.

- El instruction
- DI instruction
- LDSR reg2, 0x5 instruction (for PSW)
- The store instruction for the command register (PRCMD)
- The load, store, or bit manipulation instructions for the following registers.
  - Interrupt-related registers: Interrupt control register (xxICn), interrupt mask registers 0 to 5 (IMR0 to IMR5), in-service priority register (ISPR), power-save control register (PSC)

## **CHAPTER 8 CLOCK GENERATION FUNCTION**

The clock generator (CG) consists of a spread spectrum frequency synthesizer phase locked loop (SSCG) and a divider circuit, and generates and controls the clock supplied to the internal units as well as the CPU.

The SSCG is a spread spectrum clock generator used to suppress noise, and is effective in reducing the peak value of electromagnetic interference (EMI) noise.

### 8.1 Features

\*

\*

- SSCG output is used fixed to ×8.
- Selection of SSCG output by PLLSEL pin
   Set the PLLSEL pin as follows according to the value of fx = Input frequency to X1 and X2 pins (Fx) × 8

PLLSEL Pin	SSCG Output (fx)
0	96 MHz $\leq$ fx $\leq$ 150 MHz
1	80 MHz $\leq$ fx < 96 MHz

- Selection of frequency modulation rate (fDIT) of SSCG output The following two setting methods are available.
  - Selection by JIT0 and JIT1 pins (without modulation (frequency fixed), -1%, -3%, -5%)
  - Selection by SSCGC register (without modulation (frequency fixed), -0.5%, -1%, -2%, -3%, -4%, -5%)
- MDL-Selector Table (modulation period)

Selection by SSCGC register (13 to 27 kHz, 23 to 37 kHz, 32 to 48 kHz)

- Division function by register setting (1/1, 1/2, 1/4, 1/8)
- Clock sources

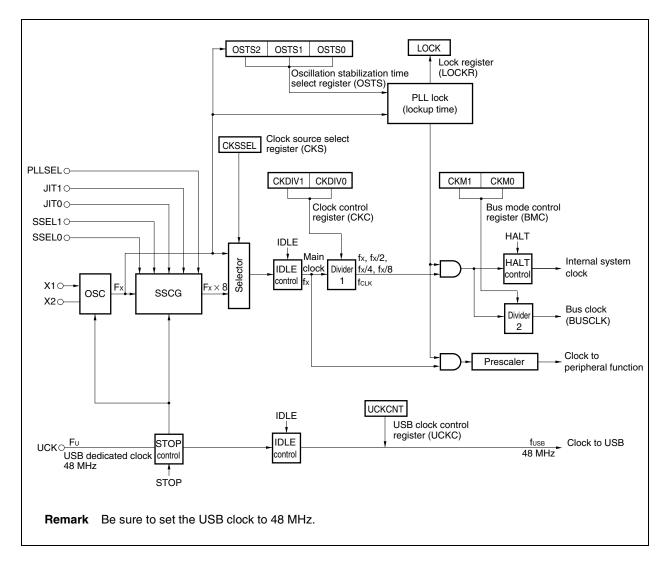

Oscillation by connecting a resonator

• Operation mode selection by register setting

The clock to be supplied to each unit is selected from the following by register setting.

- Clock output by SSCG
- Clock from OSC without passing through SSCG
- USB-dedicated clock input
- Power-save control
  - HALT mode
  - IDLE mode
  - Software STOP mode

## 8.2 Configuration

# 8.3 Control Registers

# 8.3.1 Clock control register (CKC)

The clock control register is an 8-bit register that controls the internal system clock ( $f_{CLK}$ ) in PLL mode. It can be written to only by a specific sequence so that it cannot easily be overwritten by mistake due to an inadvertent program loop.

This register can be read or written in 8-bit units.

Be sure to clear bits 7 to 2 to 0. If they are set to 1, the operation is not guaranteed.

				0	1	fx/4				
				1	0	fx/2				
				1	1	fx				
To change the internal system clock frequency in the middle of an set it to fx first, and then change the frequency as desired.							e of an operation	n, be sure to		

**Remark** fx: Main clock

- Cautions 1. Note that if the internal system clock (fcLk) is changed, the frequency of the bus clock (BUSCLK) is also changed.
  - 2. If it necessary to change the refresh interval of the SDRAM as a result of changing the internal system clock (fclk), follow this procedure.
    - <1> Mask all interrupts.

For how to disable maskable interrupts, refer to the description of interrupt mask registers 0 to 5 (IMR0 to IMR5) (7.3.5 Interrupt mask registers 0 to 5 (IMR0 to IMR5)). For how to disable non-maskable interrupts, disable multiple interrupts by setting the NP bit of the PSW to 1 (refer to 3.2.2 (2) Program status word (PSW)).

- <2> Clear the MEa bit of the BCTm register to 0 (m = 0, 1, a = 0 to 7).
- <3> Clear the RENn bit to 0 (n = 1, 3, 4, or 6).
- <4> Set the MEa bit of the BCTm register to 1 (m = 0, 1, a = 0 to 7).
- <5> Set a new value to the RCCn1, RCCn0, and RINn5 to RINn0 bits, and set the RENn bit to 1 (n = 1, 3, 4, or 6).
- <6> Write the same value currently set to the SCRn register to the SCRn register (n = 1, 3, 4, or 6).
- <7> Confirm that the WCFn bit of the SCRn register is set to 1, and access SDRAM (n = 1, 3, 4, or 6).

To change the refresh interval, set a value at which refresh can be made in time even while the interval is changed. If the refresh interval is correctly secured, the processing in <1> above may be skipped. The RFSn and BCTm registers are prohibited from being rewritten, but they can be rewritten when the refreshing interval is re-set by changing the value of the CKC register.

A register write cycle of SDRAM is generated as a result of rewriting the SCRn register (processing in <6> above), but the value of SDRAM before the RFSn and SCRn registers are re-set is retained.

Set data in the clock control register (CKC) in the following sequence.

- <1> Disable interrupts (set the NP bit of PSW to 1).
- <2> Prepare data in any one of the general-purpose registers to set in the specific register.
- <3> Write data to the command register (PRCMD).
- <4> Set the clock control register (CKC) (with the following instruction).
  - Store instruction (ST/SST instruction)
- <5> Insert the NOP instructions (5 instructions (<5> to <9>)).
- <10> Release the interrupt disabled state (clear the NP bit of PSW to 0).

```
[Sample coding] <1> LDSR rX, 5
<2> MOV 0x02, r10
<3> ST.B r10, PRCMD[r0]
<4> ST.B r10, CKC[r0]
<5> NOP
<6> NOP
<7> NOP
<8> NOP
<9> NOP
<10> LDSR rY, 5
```

Remark rX: Value written to PSW rY: Value returned to PSW

No special sequence is required to read the specific register.

- Cautions 1. If an interrupt is acknowledged between the issuance of data to the PRCMD (<3>) and writing to the specific register immediately after (<4>), the write operation to the specific register is not performed. Therefore, set the NP bit of the PSW to 1 (<1>) to disable interrupt acknowledgment. Also disable interrupt acknowledgment when selecting a bit manipulation instruction for the specific register setting.
  - Although the data written to the PRCMD register is dummy data, use the same register as the general-purpose register used in specific register setting (<4>) for writing to the PRCMD register (<3>). The same method should be applied when using a general-purpose register for addressing.
  - 3. Be sure to terminate all DMA transfers prior to the execution of the above sequence.

\*

#### 8.3.2 Clock source select register (CKS)

This 8-bit register controls supply of the main clock (fx). It can be written to only by a specific sequence so that it cannot easily be overwritten by mistake due to an inadvertent program loop.

This register can be read or written in 8-bit or 1-bit units.

- Cautions 1. With the V850E/ME2, it is not assumed that the CPU operates with the OSC output always supplied as the main clock (CKSSEL bit = 0). Therefore, be sure to confirm in the initialization sequence that the LOCK bit of the LOCKR register is 0, and then supply the main clock from the SSCG output (CKSSEL bit = 1). Otherwise, the operation will not be guaranteed.
  - 2. If the software STOP mode is released by a non-maskable interrupt request (NMI) or an unmasked maskable interrupt request, the system operates on the SSCG output clock after PLL frequency stabilization time (about 2 ms) after the count time (oscillation stabilization time set by the OSTS register) of the time base counter (TBC) has elapsed. Therefore, it is not necessary to re-set the CKS register. If the software STOP mode is released by RESET pin input, set the CKS register in accordance with the initialization sequence (see 3.4.10 Initialization sequence).

- <1> Disable interrupts (set the NP bit of PSW to 1).
- <2> Prepare data in any one of the general-purpose registers to set in the specific register.

- <4> Set the clock source select register (CKS) (with the following instruction).

Remark rX: Value written to PSW rY: Value returned to PSW

- Cautions 1. If an interrupt is acknowledged between the issuance of data to the PRCMD (<3>) and writing to the specific register immediately after (<4>), the write operation to the specific register is not performed. Therefore, set the NP bit of the PSW to 1 (<1>) to disable interrupt acknowledgment. Also disable interrupt acknowledgment when selecting a bit manipulation instruction for the specific register setting.

### 8.3.3 SSCG control register (SSCGC)

This is an 8-bit register that controls the frequency modulation rate and modulation period of SSCG output. It modulates the frequency by the frequency modulation rate (Down Spread) set by the ADJ2 to ADJ0 bits within the modulation period set by the SMDLn bit. This is effective in reducing the peak value of EMI noise. It can be written to only by a specific sequence so that it cannot easily be overwritten by mistake due to an inadvertent program loop. This register can be read or written in 8-bit units.

Caution The SSCGC register can be set only when OSC output is supplied as the main clock (CKSSEL bit of CKS register = 0). If the setting of the SSCGC register is changed, the SSCG is unlocked (LOCK bit of LOCKR register = 1). Be sure to confirm that the LOCK bit = 0 before starting to supply SSCG output as the main clock (CKSSEL bit = 1). Otherwise, the operation will not be guaranteed.

# Remark rX: Value written to PSW

rY: Value returned to PSW

No special sequence is required to read the specific register.

- Cautions 1. If an interrupt is acknowledged between the issuance of data to the PRCMD (<3>) and writing to the specific register immediately after (<4>), the write operation to the specific register is not performed. Therefore, set the NP bit of the PSW to 1 (<1>) to disable interrupt acknowledgment. Also disable interrupt acknowledgment when selecting a bit manipulation instruction for the specific register setting.
  - 2. Although the data written to the PRCMD register is dummy data, use the same register as the general-purpose register used in specific register setting (<4>) for writing to the PRCMD register (<3>). The same method should be applied when using a general-purpose register for addressing.
  - 3. Be sure to terminate all DMA transfers prior to the execution of the above sequence.

## 8.3.4 USB clock control register (UCKC)

This register is used to select the clock source of the USB clock. Be sure to input fuse at 48 MHz. This register can be read or written in 8-bit or 1-bit units.

Be sure to clear the bits of this register other than bit 7 to 0. If they are set to 1, the operation is not guaranteed.

# Caution When using the USB function, be sure to set (1) the UCKCNT bit. If the registers related to the USB function are read while the UCKCNT bit is 0, 0 is read.

## 8.3.5 Lock register (LOCKR)

The lockup time (frequency stabilization time: approx. 2 ms) is the time from when the power is turned on or software STOP mode is released until the phase locks at the prescribed frequency. The state until this stabilization occurs is called the lockup state, and the stabilized state is called the locked state.

The lock register (LOCKR) has a LOCK flag that indicates that the PLL is in the lock wait state. This register is read-only in 8-bit or 1-bit units.

Caution If the phase is locked, the LOCK flag is cleared to 0. If it is unlocked later because of a standby status, writing to SSCGC register, or  $\overrightarrow{\text{RESET}}$  input, the LOCK flag is set to 1. If the phase is unlocked by a cause other than these, however, the LOCK flag is not affected (LOCK = 0).

If some other factor operates to cause an unlock state to occur, for control processing that depends on software execution speed, such as real-time processing, be sure to judge the LOCK flag by software immediately after operation begins and start processing after the PLL is locked.

On the other hand, static processing such as the setting of internal hardware or the initialization of register data or memory data can be executed without waiting for the LOCK flag to be reset to 0.

# 8.3.6 Oscillation stabilization time select register (OSTS)

This is an 8-bit register that specifies the oscillation stabilization time.

The OSTS register is used to make sure that the oscillation stabilization time of the oscillator elapses when the software STOP mode is released. After the software STOP mode is released, the oscillation stabilization time is counted by the time base counter (TBC), and program execution is started about 2 ms later.

This register can be read or written in 8-bit units.

The operation is not guaranteed if fclk (MAX.) < fx.

Make sure that fx does not exceed the guaranteed operating frequency of each product.

## 8.5 Operating Clock Provisions

٠

SSCG consists of a multiplier that multiplies the OSC clock by eight and a modulation circuit for frequency diffusion. The multiplier that multiplies the OSC clock generates an output error of up to  $\pm 150$  ps in the output period because of its circuit characteristics.

The modulation circuit adds the modulation error with respect to the set modulation rate, which varies depending on the modulation rate.

Therefore, the output frequency ( $f_{CLK}$ ) of BUSCLK, which outputs a clock via SSCG, and the operating frequency of the on-chip peripheral I/O (main clock ( $f_x$ ) of timers C, D, and ENC1, PWM unit, CSI3, UARTB, and A/D converter) are affected by this error. When calculating the frequency of each signal, therefore, be sure to take this error into consideration.

The methods of calculating the output period and output frequency at each modulation rate are shown below.

# (1) Minimum value of operating frequency (fmin)

Modulation Rate of SSCG Output (%)	Parameter	Output Period: T <sub>MAX</sub> (ns)	Output Frequency (MHz)
No modulation	1.00000	$(1/f_x) \times 10^3 + 0.15$	$(1/T_{MAX}) \times 10^3$

-5.00	0.96140	$\{1(0.93860 \times fx)\} \times 10^3 + 0.15$	$(1/T_{MAX}) \times 10^3$

#### (2) Maximum value of operating frequency (fMAX)

Modulation Rate of SSCG Output (%)	Parameter	Output Period: TMAX (ns)	Output Frequency (MHz)
No modulation	1.00000	$(1/f_x) \times 10^3 - 0.15$	(1/T <sub>MIN</sub> ) × 10 <sup>3</sup>

# (3) Average operating frequency (fave)

The average operating frequency can be calculated by this expression.

Average operating frequency  $(f_{AVE}) = (f_{MIN} + f_{MAX})/2$ 

The average operating frequency is in one period of the modulation period set by the SMDL1 and SMDL0 bits of the SSCGC register. The average operating frequency in a period shorter than the modulation period may have a relatively larger error than the result of the above expression.

## 8.5.1 Calculating BUSCLK frequency

If the modulation function of SSCG is used, the internal system clock frequency (fcLK) from which BUSCLK is generated fluctuates. Exercise care in calculating the frequency of BUSCLK.

The following table shows the frequency fluctuation of BUSCLK.

BMC F	legister	BUS	CLK Frequency (	MHz)
CKM1	CKM1	Min.	Тур.	Max.
0	0	fмin	fave	fмах
0	1	fміл/2	fave/2	fмах/2
1	0	fміл/З	fave/3	fмах/З
1	1	fmin/4	fave/4	fmax/4

## Table 8-3. Frequency Fluctuation of BUSCLK

## 8.5.2 Calculating operating clock frequency of each on-chip peripheral function

When the modulation function of SSCG is used, the main clock (fx) from which the operating clock of each on-chip peripheral function is generated fluctuates. Note (1) to (8) below.

(1) Count period of timer C:

Period of count clock frequency (set by the CSCn2 to CSCn0 bits of the TMCCn0 register) when input clock is specified (ETICn bit of the TMCCn1 register = 0) (n = 0 to 5)

The count period can be calculated from the average operating frequency.

However, the average operating frequency is in one period of the modulation period set by the SMDL1 and SMDL0 bits of the SSCGC register. Note that the average operating frequency may have a relatively larger error than the result of calculation during a count operation in a period shorter than the modulation period. If it is necessary to guarantee an absolute value for the count operation, it is recommended to set appropriate counts during operation at fmin if the counting operation is performed within a specific time and during operation at fmax if the operation is performed for longer than a specific time.

Do not use the modulation function of SSCG if a high-accuracy count operation is necessary.

(2) Count period of timer D:

Period of count clock frequency (set by CSDn2 to CSDn0 bits of the TMCDn register) (n = 0 to 3)

The count period can be calculated from the average operating frequency.

However, the average operating frequency is in one period of the modulation period set by the SMDL1 and SMDL0 bits of the SSCGC register. Note that the average operating frequency may have a relatively larger error than the result of calculation during a count operation in a period shorter than the modulation period. If it is necessary to guarantee an absolute value for the count operation, it is recommended to set appropriate equation during a count is necessary to guarantee an absolute value for the count operation, it is recommended to set appropriate equation.

counts during operation at fMIN if the counting operation is performed within a specific time and during operation at fMAX if the operation is performed for longer than a specific time.

Do not use the modulation function of SSCG if a high-accuracy count operation is necessary.

(3) Count period of timer ENC1:

Period of count clock frequency (set by PRM1n2 to PRM1n0 bits of the PRM1n register) when generalpurpose timer mode is specified (T1CMDn bit of the TUM1n register = 0) (n = 0, 1)

The count period can be calculated from the average operating frequency.

However, the average operating frequency is in one period of the modulation period set by the SMDL1 and SMDL0 bits of the SSCGC register. Note that the average operating frequency may have a relatively larger error than the result of calculation during a count operation in a period shorter than the modulation period.

If it is necessary to guarantee an absolute value for the count operation, it is recommended to set appropriate counts during operation at fmin if the counting operation is performed within a specific time and during operation at fmax if the operation is performed for longer than a specific time. Duty setting is guaranteed during either high level output or low level output when PWM output is performed.

Do not use the modulation function of SSCG if a high-accuracy count operation is necessary.

(4) Pulse output period of PWM unit:

Period of operating clock frequency (set by the CKSPn1 and CKSPn0 bits of the PWMCn register) (n = 0, 1)

The pulse output period can be calculated from the average operating frequency.

However, the average operating frequency is in one period of the modulation period set by the SMDL1 and SMDL0 bits of the SSCGC register. Note that the average operating frequency may have a relatively larger error than the result of calculation when a pulse with a period shorter than the modulation period is output.

If it is necessary to guarantee an absolute value for the pulse output, it is recommended to set appropriate counts during operation at fmin if the counting operation is performed within a specific time and during operation at fmax if the operation is performed for longer than a specific time. Duty setting is guaranteed during either high level output or low level output when PWM output is performed.

Do not use the modulation function of SSCG if a high-accuracy pulse output is necessary.

(5) Serial communication (transmission, reception, or transmission/reception) transfer rate of CSI3: Period of base clock frequency (CKS3n2 to CKS3n0 of the CSIC3n register = other than 111) (n = 0, 1) with master mode specified

The transfer rate can be calculated from the average operating frequency.

However, the average operating frequency is in one period of the modulation period set by the SMDL1 and SMDL0 bits of the SSCGC register. Note that the average operating frequency may have a relatively larger error than the result of calculation at a transfer rate shorter than the modulation period.

If it is necessary to guarantee an absolute value for the transfer rate, it is recommended to set an appropriate transfer rate during operation at fmin for the minimum transfer rate and during operation at fmax for the maximum transfer rate.

(6) Serial communication (transmission or reception) transfer rate of UARTB:
 Period of serial transfer speed (set by the UBnBRS15 to UBnBRS0 bits of the UBnCTL2 register) (n = 0, 1)

Set the value of the transfer rate (set value (k) of the UBnCTL2 register) so that the permissible maximum and minimum baud rate errors are satisfied at both fmin and fmax. Here is a calculation example.

- <1> Determine the set value (k) of the UBnCTL2 register from the calculation result of the expression "Target baud rate × 2/fAVE (Hz)".
- <2> Calculate the actual baud rate value at fMAX and fMIN, by using the set value (k) calculated in <1> above.
- <3> Check that the result of calculation in <2> above satisfies the allowable maximum/minimum baud rate error.
- <4> From <1> to <3>, calculate the set value of the transfer rate (set value (k) of the UBnCTL2 register).
- Caution Change the modulation rate of SSCG if the set value (set value (k) of the UBnCTL2 register) of the transfer rate that satisfies the above calculation method cannot be obtained.

#### (Example)

- fx = 150 MHz: Setting of modulation rates of 4% and 5% is prohibited.
- fx = 133 MHz: Setting of modulation rates of 4% and 5% is prohibited.
- fx = 100 MHz: Setting of modulation rate of 5% is prohibited.
- (7) A/D converter:

#### Conversion time

Calculate the set value (2 to 10  $\mu$ s) of the A/D conversion time (set by the FR3 to FR0 bits of the ADM1 register) by fave (calculation by fmin and fmax is not necessary).

(8) Digital noise elimination time

Calculate the minimum noise elimination time set by the NCWCn and NCW1m registers at  $f_{MAX}$  and the maximum noise elimination time at  $f_{MIN}$  (n = 0 to 3, m = 0, 1).

## 8.6 Power-Save Control

#### 8.6.1 Overview

The power-save function has the following three modes.

#### (1) HALT mode

In this mode, the clock generator (oscillator (OSC, SSCG) and PLL synthesizer) continues to operate, but the CPU's operation clock stops. Since the supply of clocks to on-chip peripheral functions other than the CPU continues, operation continues. The power consumption of the overall system can be reduced by intermittent operation using a combination of the HALT mode and the normal operation mode.

The system is switched to HALT mode by a specific instruction (the HALT instruction).

#### (2) IDLE mode

In this mode, the clock generator (oscillator (OSC, SSCG) and PLL synthesizer) continues to operate, but the supply of internal system clocks is stopped, which causes the overall system to stop.

When the system is released from IDLE mode, it can be switched to normal operation mode quickly because the oscillator's oscillation stabilization time does not need to be secured.

The system is switched to IDLE mode by a PSMR register setting.

IDLE mode is located midway between software STOP mode and HALT mode in relation to the clock stabilization time and current consumption. It is used for situations in which a low-current-consumption mode is to be used and the clock stabilization time is to be eliminated after the mode is released.

# (3) Software STOP mode

In this mode, the overall system is stopped by stopping the clock generator (oscillator (OSC, SSCG) and PLL synthesizer). The system enters an ultra-low-power-consumption state in which only leakage current is lost. The system is switched to software STOP mode by a PSMR register setting. The PLL synthesizer's clock output is stopped at the same time the oscillator is stopped. After software STOP mode is released by RESET input, the oscillator's oscillation stabilization time must be secured until the system clock stabilizes. When the software STOP mode is released by the non-maskable interrupt request (NMI) or an unmasked maskable interrupt request, program execution is started about 2 ms after the count time of the time base counter (TBC) elapses.

Figure 8-1 shows the operation of the clock generator in normal operation mode, HALT mode, IDLE mode, and software STOP mode.

An effective low power consumption system can be realized by combining these modes and switching modes according to the required use.

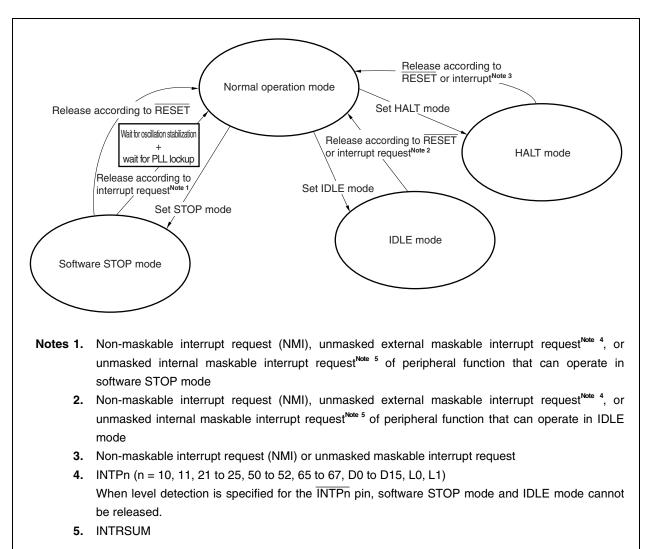

Figure 8-1. Power-Save Mode State Transition Diagram

## 8.6.2 Control registers

# (1) Power-save mode register (PSMR)

This is an 8-bit register that controls power-save mode. It is effective only when the STP bit of the PSC register is set to 1.

Writing to the PSMR register is executed by the store instruction (ST/SST instruction) and a bit manipulation instruction (SET1/CLR1/NOT1 instruction).

This register can be read or written in 8-bit or 1-bit units.

Be sure to clear bits 7, 5, and 4 to 0. If they are set to 1, the operation is not guaranteed.

	7	6	5	4	3	2	1	<0>	Address	After reset
PSMR	0	0	0	0	0	0	0	PSM	FFFFF820H	00H
Bit posi	tion	Bit name		Function						
Bit posi 0	tion	Bit name PSM	-	Function Specifies IDLE mode or software STOP mode. 0: Switches the system to IDLE mode						
				1: Switches the system to software STOP mode						

# (2) Command register (PRCMD)

This is an 8-bit register that is used to set protection for write operations to registers that can significantly affect the system so that the application system is not halted unexpectedly due to an inadvertent program loop.

Writing to the first specific register (power-save control register (PSC), etc.) is only valid after first writing to the PRCMD register. Because of this, the register value can be overwritten only by the specified sequence, preventing an illegal write operation from being performed.

This register is write-only in 8-bit units (when it is read, undefined data is read out).

	7	6	5	4	3	2	1	0	Address	After reset
PRCMD	RREG7	RREG6	RREG5	RREG4	RREG3	RREG2	RREG1	RREG0	FFFFF1FCH	Undefined
Bit posit	ion	Bit name		Function						
7 to 0	RI	REG7 to	Regist	Registration code (arbitrary 8-bit data)						
	RI	REG0	EG0 The specific register targeted is as follows.							
			• Pc	Power-save control register (PSC)						
			• CI	Clock control register (CKC)						
			• CI	Clock source select register (CKS)						
			• SS	SSCG control register (SSCGC)						

# (3) Power-save control register (PSC)

This is an 8-bit register that controls the power-save function.

If interrupts are enabled by the setting of the NMIM and INTM bits, the software STOP mode can be released by an interrupt request (except when interrupt servicing is disabled by the interrupt mask registers (IMR0 to IMR5)).

The software STOP mode is specified by the setting of the STP bit.

This register, which is one of the specific registers, is valid only when accessed in a specific sequence during a write operation.

This register can be read or written in 8-bit or 1-bit units.

Be sure to clear bits 7 and 6 to 0. If they are set to 1, the operation is not guaranteed.

# Cautions 1. It is impossible to set the STP bit and the NMIM or INTM bit at the same time. Be sure to set the STP bit after setting the NMIM or INTM bit.

2. The software STOP mode is not released by an interrupt request for which the NMIM and INTM bits are set to 1 because this interrupt request is invalid (it is not held pending).

	7	6	<5>	<4>	3	2	<1>	0	Address	After reset
PSC	0	0	NMIM	INTM	0	0	STP	0	FFFFF1FEH	00H

Bit position	Bit name	Function
5	NMIM	This is the enable/disable setting bit for standby mode release using the valid edge input of NMI. 0: Release by NMI enabled 1: Release by NMI disabled
4	INTM	This is the enable/disable setting for standby mode release using an unmasked maskable interrupt (INTPn) (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, L1). 0: Release by maskable interrupt enabled 1: Release by maskable interrupt disabled
1	STP	Indicates the standby mode status. If 1 is written to this bit, the system enters IDLE or software STOP mode (set by the PSM bit of the PSMR register). When standby mode is released, this bit is automatically rese to 0. 0: Standby mode is released 1: Standby mode is in effect

Set data in the power-save control register (PSC) in the following sequence.

<1> Set the power-save mode register (PSMR) (with the following instructions).

- Store instruction (ST/SST instruction)
- Bit manipulation instruction (SET1/CLR1/NOT1 instruction)
- <2> Prepare data in any one of the general-purpose registers to set to the specific register.
- <3> Write data to the command register (PRCMD).
- <4> Set the power-save control register (PSC) (with the following instructions).

No special sequence is required to read the specific register.

- Cautions 1. A store instruction for the command register does not acknowledge interrupts. This coding is made on assumption that <3> and <4> above are executed by the program with consecutive store instructions. If another instruction is set between <3> and <4>, the above sequence may become ineffective when the interrupt is acknowledged by that instruction, and a malfunction of the program may result.
  - 2. Although the data written to the PRCMD register is dummy data, use the same register as the general-purpose register used in specific register setting (<4>) for writing to the PRCMD register (<3>). The same method should be applied when using a general-purpose register for addressing.
  - 3. At least 5 NOP instructions must be inserted after executing a store instruction to the PSC register to set software STOP or IDLE mode.
  - 4. Be sure to terminate all DMA transfers prior to the execution of the above sequence.

## 8.6.3 HALT mode

### (1) Setting and operation status

In HALT mode, the clock generator (oscillator (OSC, SSCG) and PLL synthesizer) continues to operate, but the operation clock of the CPU is stopped. Since the supply of clocks to on-chip peripheral functions other than the CPU continues, operation continues. The power consumption of the overall system can be reduced by setting the system to HALT mode while the CPU is idle.

The system is switched to HALT mode by the HALT instruction.

Although program execution stops in HALT mode, the contents of all registers, internal data RAM, internal instruction RAM, and ports are maintained in the state they were in immediately before HALT mode began. Also, operation continues for all on-chip peripheral functions (other than ports) that do not depend on CPU instruction processing. The following shows the status of each hardware unit in HALT mode.

# Cautions 1. If the HALT instruction is executed while an interrupt is being held pending, the HALT mode is set once but it is immediately released by the pending interrupt request.

2. At least 5 NOP instructions must be inserted after executing a HALT instruction.

## (2) Release of HALT mode

HALT mode is released by a non-maskable interrupt request, an unmasked maskable interrupt request, or RESET pin input.

(a) Release according to a non-maskable interrupt request or an unmasked maskable interrupt request

HALT mode is released by a non-maskable interrupt request or by an unmasked maskable interrupt request regardless of the priority. The operation after release is as follows.

Non-maskable interrupt request	Branch to handler address		
Maskable interrupt request	Branch to handler address or execute next instruction	Execute next instruction	

Table 8-5. Operation After HALT Mode Is Released by Interrupt Request

However, if the system is set to HALT mode during an interrupt servicing routine, operation will differ as follows.

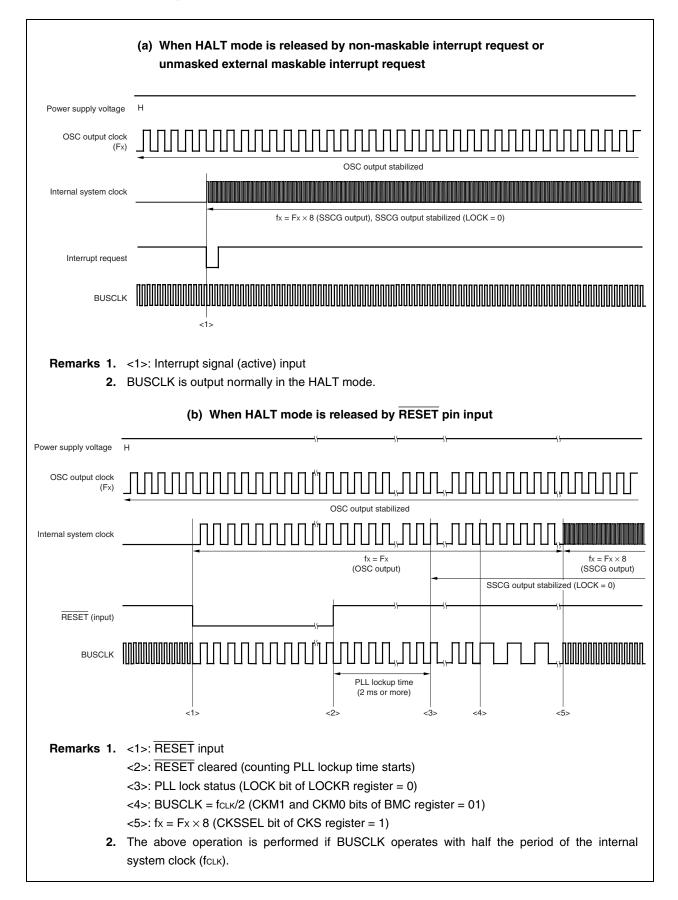

- (i) If an interrupt request is generated with a lower priority than that of the maskable interrupt request that is currently being serviced, HALT mode is released, but the newly generated interrupt request is not acknowledged. The new interrupt request is held pending.
- (ii) If an interrupt request (including non-maskable interrupt requests) is generated with a higher priority than that of the maskable interrupt request that is currently being serviced, HALT mode is released and the newly generated interrupt request is acknowledged.

## (b) Release according to RESET pin input

This is the same as a normal reset operation.

The BUSCLK operation when the HALT mode is released is illustrated below.

## 8.6.4 IDLE mode

#### (1) Setting and operation status

In this mode, the entire system is stopped with the clock generator (oscillator (OSC, SSCG) and PLL synthesizer) continuing to operate and clock supply to the CPU and other on-chip peripheral functions stopped.

When IDLE mode is released, the system can be switched to normal operation mode quickly because the oscillator's oscillation stabilization time or the PLL lockup time does not need to be secured.

The system is switched to IDLE mode by setting the PSC or PSMR register using a store instruction (ST or SST instruction) or a bit manipulation instruction (SET1, CLR1, or NOT1 instruction) (see **8.6.2 Control registers**).

In IDLE mode, program execution is stopped, and the contents of all registers, internal data RAM, internal instruction RAM, and ports are maintained in the state they were in immediately before execution stopped. The operation of CPU and other on-chip peripheral functions is stopped. However, the on-chip peripheral functions that can operate on the external clock continue operating.

The following shows the status of each hardware unit in IDLE mode.

# Caution Insert at least 5 NOP instructions after the instruction that stores data in the PSC register to set the IDLE mode.

# Table 8-6. Operation Status in IDLE Mode

## (2) Release of IDLE mode

The IDLE mode is released by a non-maskable interrupt request, an unmasked external maskable interrupt request (INTPn)<sup>Note</sup>, an unmasked internal maskable interrupt request of a peripheral function that can operate in the IDLE mode (INTRSUM), and  $\overline{\text{RESET}}$  pin input (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, or L1).

Note When level detection is set, the IDLE mode cannot be released.

# (a) Release according to a non-maskable interrupt request or an unmasked maskable interrupt request

IDLE mode can be released by an interrupt request only when it has been set with the INTM and NMIM bits of the PSC register cleared to 0.

IDLE mode is released by a non-maskable interrupt request, an unmasked external maskable interrupt request (INTPn), or an unmasked internal maskable interrupt request of a peripheral function that can operate in the IDLE mode (INTRSUM) regardless of the priority (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, or L1). The operation after release is as follows.

Table 8-7.	Operation	After IDLE Mod	e is Released b	y Interrupt Request
1 4 5 1 5 7 1	operation	AILOI IDEE IIIOG		y mitori apt moquoot

Release Source	Enable Interrupt (EI) Status	Disable Interrupt (DI) Status	
Non-maskable interrupt request	Branch to handler address		
Maskable interrupt request	Branch to handler address or execute next instruction	Execute next instruction	

However, if the system is set to IDLE mode during an interrupt servicing routine, operation will differ as follows.

- (i) If an interrupt request is generated with a lower priority than that of the maskable interrupt request that is currently being serviced, IDLE mode is released, but the newly generated interrupt request is not acknowledged. The new interrupt request is held pending.
- (ii) If an interrupt request (including non-maskable interrupt requests) is generated with a higher priority than that of the maskable interrupt request that is currently being serviced, IDLE mode is released and the newly generated interrupt request is acknowledged.

If the system is set to IDLE mode during an NMI servicing routine, IDLE mode is released, but the interrupt is not acknowledged (interrupt is held pending).

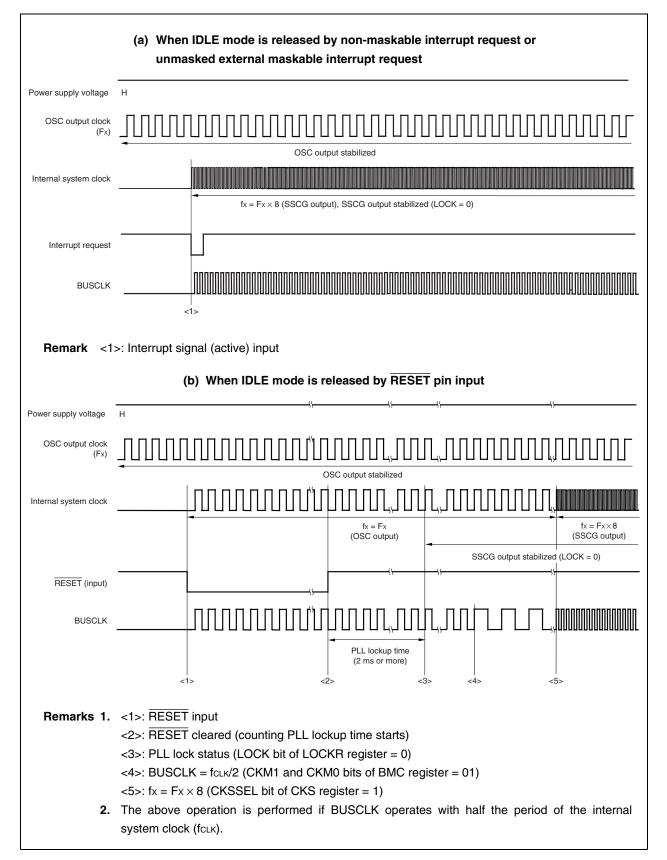

Interrupt servicing that is started when IDLE mode is released by NMI pin input is handled in the same way as normal NMI interrupt servicing that occurs during an emergency (because the NMI interrupt handler address is unique). Therefore, when a program must be able to distinguish between these two situations, a software status must be prepared in advance and that status must be set before setting the PSMR register using a store instruction or a bit manipulation instruction. By checking for this status during NMI interrupt servicing, an ordinary NMI can be distinguished from the processing that is started when IDLE mode is released by NMI pin input.

## (b) Release according to RESET pin input

This is the same as a normal reset operation.

The BUSCLK operation when the IDLE mode is released is illustrated below.

#### 8.6.5 Software STOP mode

#### (1) Setting and operation status

In software STOP mode, the clock generator (oscillator (OSC, SSCG) and PLL synthesizer) is stopped. The overall system is stopped, and ultra-low power consumption is achieved in which only leakage current is lost. The system is switched to software STOP mode by using a store instruction (ST or SST instruction) or bit manipulation instruction (SET1, CLR1, or NOT1 instruction) to set the PSC and PSMR registers (see **8.6.2 Control registers**).

The oscillator's oscillation stabilization time and PLL frequency stabilization time must be secured after software STOP mode is released.

If the software STOP mode is released by an unmasked maskable interrupt request<sup>Note</sup>, program execution is started after the PLL lockup time (about 2 ms) has elapsed after the count time of the time base counter (TBC) (time set by the OSTS register) elapses.

Although program execution stops in software STOP mode, the contents of all registers, internal data RAM, internal instruction RAM, and ports are maintained in the state they were in immediately before software STOP mode began. The operation of CPU and other on-chip peripheral functions is stopped.

The following shows the status of each hardware unit in software STOP mode.

- Note INTP10, INTP11, INTP21 to INTP25, INTP50 to INTP52, INTP65 to INTP67, INTPD0 to INTPD15, INTPL0, INTPL1, INTRSUM
- Cautions 1. Insert at least 5 NOP instructions after the instruction that stores data in the PSC register to set the software STOP mode.
  - If the software STOP mode is released by an unmasked maskable interrupt request, the external bus continues to operate in the same status as in the software STOP mode during the count time (time set by the OSTS register) of the time base counter (TBC) and the PLL lockup time.

# Table 8-8. Operation Status in Software STOP Mode

## (2) Release of software STOP mode

The software STOP mode is released by a non-maskable interrupt input, an unmasked external maskable interrupt request  $(INTPn)^{Note}$ , an unmasked internal maskable interrupt request of a peripheral function that can operate in the software STOP mode (INTRSUM), or RESET pin input (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, or L1). When the software STOP mode is released by RESET pin input, it is necessary to make sure that the oscillation stabilization time of the oscillator elapses. When the software STOP mode is released by the non-maskable interrupt or an unmasked maskable interrupt request, program execution starts after about 2 ms after the count time of the time base counter (TBC) elapses.

Note When level detection is set, the software STOP mode cannot be released.

# (a) Release according to a non-maskable interrupt request or an unmasked maskable interrupt request

The software STOP mode can be released by an interrupt request only when it has been set with the INTM and NMIM bits of the PCS register cleared to 0.

Software STOP mode is released by a non-maskable interrupt request, an unmasked external maskable interrupt request (INTPn), or an unmasked internal maskable interrupt request of a peripheral function that can operate in the software STOP mode (INTRSUM) regardless of the priority (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, or L1). The operation after release is as follows.

Release Source	Enable Interrupt (EI) Status	Disable Interrupt (DI) Status
Non-maskable interrupt request	Branch to handler address	
Maskable interrupt request	Branch to handler address or execute next instruction	Execute next instruction

#### Table 8-9. Operation After Software STOP Mode Is Released by Interrupt Request

The operation is performed as shown below if the software STOP mode is set in an interrupt servicing routine.

	request	Same	acknowledged (is neid pending).		
		High	Interrupt request is acknowledged when software STOP mode is released.		

 Table 8-10. Operation If Software STOP Mode Is Set in Interrupt Servicing Routine

Notes 1. Priority of interrupt (being serviced) when software STOP mode is set

- 2. When the ID bit of the PSW is 1 (disabling acknowledging interrupt)
- 3. When the ID bit of the PSW is 0 (enabling acknowledging interrupt)

**Remark** The software STOP mode is released by NMI regardless of the value of the NP bit of the PSW.

If the system is set to software STOP mode during an NMI servicing routine, software STOP mode is released, but the interrupt is not acknowledged (interrupt is held pending).

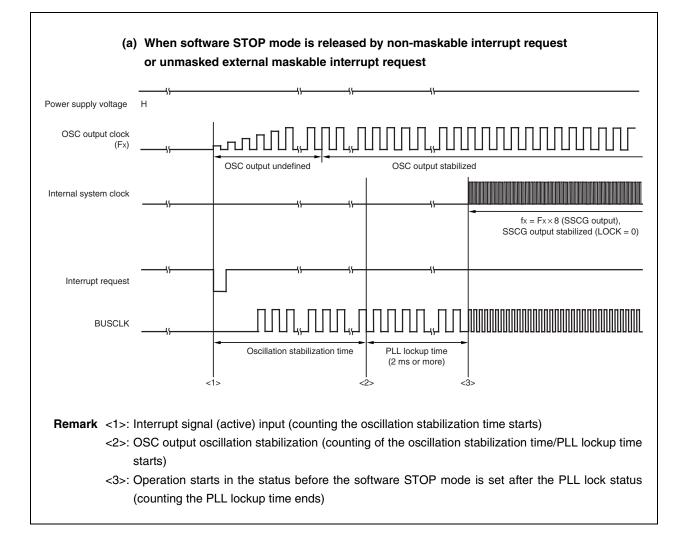

Interrupt servicing that is started when software STOP mode is released by NMI pin input is handled in the same way as normal NMI interrupt servicing that occurs during an emergency (because the NMI interrupt handler address is unique). Therefore, when a program must be able to distinguish between these two situations, a software status must be prepared in advance and that status must be set before setting the PSMR register using a store instruction or a bit manipulation instruction.

By checking for this status during NMI interrupt servicing, an ordinary NMI can be distinguished from the servicing that is started when software STOP mode is released by NMI pin input.

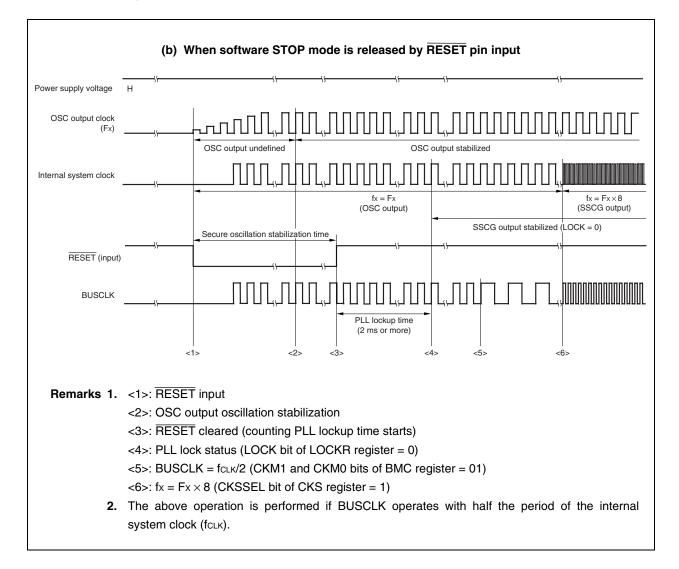

#### (b) Release according to RESET pin input

This is the same as a normal reset operation.

The BUSCLK operation when the software STOP mode is released is illustrated below.

## Figure 8-4. BUSCLK Operation When Software STOP Mode Is Released (1/2)

#### Figure 8-4. BUSCLK Operation When Software STOP Mode Is Released (2/2)

## 8.7 Securing Oscillation Stabilization Time

#### 8.7.1 Oscillation stabilization time security specification

When the software STOP mode is released by a non-maskable interrupt request, an unmasked external maskable interrupt request  $(INTPn)^{Note}$  (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, or L1), or an unmasked internal maskable interrupt request of a peripheral function that can operate in the software STOP mode (INTRSUM), the oscillation stabilization time set by the OSTS register is secured (see **Figure 8-4 (a)**). About 2 ms after that, program execution is started. When the software STOP mode is released by **RESET** pin input, the oscillation stabilization time does not elapse. Therefore, secure the oscillation stabilization time by the low-active width of **RESET** (see **Figure 8-4 (b)**).

The internal time base counter (TBC) is used as a timer that counts and secures the oscillation stabilization time.

Oscillation stabilization time = Count time of TBC

Note When level detection is set, the software STOP mode cannot be released.

#### 8.7.2 Time base counter (TBC)

The time base counter (TBC) is used to secure the oscillator's oscillation stabilization time when software STOP mode is released.

The TBC counts the oscillation stabilization time after software STOP mode is released, and program execution begins after the count is completed.

The TBC count clock is selected according to the OSTS2 to OSTS0 bits of the OSTS register, and the next counting time can be set.

## CHAPTER 9 TIMER/COUNTER FUNCTION (REAL-TIME PULSE UNIT)

## 9.1 Timer C

## 9.1.1 Features

Timer C is a 16-bit timer/counter that can perform the following operations.

- Interval timer function
- PWM output
- External signal cycle measurement

## 9.1.2 Function overview

- 16-bit timer/counter: 6 channels (no capture operation for 2 channels)
- Capture/compare common registers: 12 sources
- Interrupt request sources
  - Capture/match interrupt requests: 12 sources
     Capture register: Generates INTCCCm0 or INTCCCm1 at INTPCm0 or INTPCm1 input
     Compare register: Generates INTCCCn0 or INTCCCn1 at match signal of CCCn0 or CCCn1
  - Overflow interrupt requests: 6 sources
- Timer/counter count clock sources: 2 types (Selection of external pulse input or main clock division)
- Either free-running mode or overflow stop mode can be selected as the operation mode when the timer/counter overflows
- Timer/counter can be cleared by a match of the timer/counter and a compare register
- External pulse outputs: 6

**Remark** m = 0 to 3, n = 0 to 5

Table 9-1. Timer C Configuration

Remark fx: Main clock

S/R: Set/reset

## (1) Timer C (16-bit timer/counter)

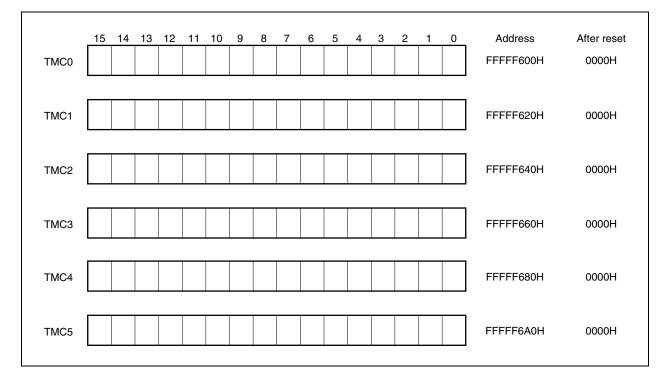

## 9.1.4 Timer C

## (1) Timers C0 to C5 (TMC0 to TMC5)

TMCn functions as a 16-bit free-running timer or as an event counter for an external signal. Besides being mainly used for cycle measurement, TMCn can be used as pulse output (n = 0 to 5). TMCn is read-only in 16-bit units.

## Cautions 1. The TMCn register can only be read. If the TMCn register is written, the subsequent operation is undefined.

2. If the CAECn bit of the TMCCn0 register is cleared to 0, a reset is performed asynchronously.

TMCn performs the count-up operations of an internal count clock or external count clock. Timer start and stop are controlled by the CECn bit of timer mode control register Cn0 (TMCCn0) (n = 0 to 5).

The internal or external count clock is selected by the ETICn bit of timer mode control register Cn1 (TMCCn1) (n = 0 to 5).

#### (a) Selection of the external count clock

TMCn operates as an event counter.

When the ETICn bit of timer mode control register Cn1 (TMCCn1) is set to 1, TMCm counts the valid edges of the external clock input (TICm), synchronized with the internal count clock. The valid edge is specified by valid edge select register Cm (SESCm) (m = 0 to 3, n = 0 to 5).

Caution When the INTPCm0/TICm pin is used as TICm (external clock input pin), disable the INTPCm0 interrupt or set CCCm0 to compare mode (m = 0 to 3, n = 0 to 5).

## (b) Selection of the internal count clock

TMCn operates as a free-running timer.

When an internal clock is specified as the count clock by timer mode control register Cn1 (TMCCn1), TMCn is counted up for each input clock cycle specified by the CSCn0 to CSCn2 bits of the TMCCn0 register (n = 0 to 5).

Division by the prescaler can be selected for the count clock from among  $f_x/8$ ,  $f_x/16$ ,  $f_x/32$ ,  $f_x/64$ ,  $f_x/128$ ,  $f_x/256$ ,  $f_x/512$ , and  $f_x/1,024$  by the TMCCn0 register ( $f_x$ : main clock).

An overflow interrupt can be generated if the timer overflows. Also, the timer can be stopped following an overflow by setting the OSTCn bit of the TMCCn1 register to 1.

#### Caution The count clock cannot be changed while the timer is operating.

The conditions when the TMCn register becomes 0000H are shown below.

#### (a) Asynchronous reset

- CAECn bit of TMCCn0 register = 0
- Reset input

#### (b) Synchronous reset

- CECn bit of TMCCn0 register = 0
- The CCCn0 register is used as a compare register, and the TMCn and CCCn0 registers match when clearing the TMCn register is enabled (CCLRCn bit of the TMCCn1 register = 1)

## (2) Capture/compare registers Cn0 and Cn1 (CCCn0 and CCCn1) (n = 0 to 5)

These capture/compare registers (Cn0 and Cn1) are 16-bit registers.

They can be used as capture registers or compare registers according to the CMSCn0 and CMSCn1 bit specifications of timer mode control register Cn1 (TMCCn1) (n = 0 to 5).

These registers can be read or written in 16-bit units. (However, write operations can only be performed in compare mode.)

## Caution The CCC40, CCC41, CCC50, and CCC51 registers can only be used as compare registers. They cannot be used as capture registers.

CCC0n	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address FFFFF602H, FFFFF604H	After reset 0000H
CCC1n																	FFFF622H, FFFFF624H	0000H
CCC2n																	FFFFF642H, FFFFF644H	0000H
CCC3n																	FFFF662H, FFFFF664H	0000H
CCC4n																	FFFFF682H, FFFFF684H	0000H
CCC5n																	FFFF6A2H, FFFFF6A4H	0000H
Remark	<b>(</b> n =	= 0, 1	I															

## (a) Setting these registers as capture registers (CMSCn0 and CMSCn1 of TMCCn1 = 0)

When these registers are set as capture registers, the valid edges of the corresponding external interrupt signals INTPCm0 and INTPCm1 are detected as capture triggers. The timer TMCm is synchronized with the capture trigger, and the value of TMCm is latched in the CCCm0 and CCCm1 registers (capture operation) (m = 0 to 3, n = 0 to 5).

The valid edge of the INTPCm0 pin is specified (rising edge, falling edge, or both rising and falling edges) according to the IESC0m1 and IESC0m0 bits of the SESCm register, and the valid edge of the INTPCm1 pin is specified according to the IESC1m1 and IESC1m0 bits of the SESCm register.

The capture operation is performed asynchronously to the count clock. The latched value is held in the capture register until another capture operation is performed.

When the CAECn bit of timer mode control register Cn0 (TMCCn0) is 0, 0000H is read.

If these registers are specified as capture registers, an interrupt is generated by detecting the valid edge of signals INTPCm0 and INTPCm1.

Caution If the capture operation contends with the timing of disabling the TMCm register from counting (when the CECn bit of the TMCCn0 register = 0), the captured data becomes undefined. In addition, the INTCCCm0 and INTCCCm1 interrupts do not occur (m = 0 to 3, n = 0 to 5).

#### (b) Setting these registers as compare registers (CMSCn0 and CMSCn1 of TMCCn1 = 1)

When these registers are set as compare registers, the TMCn and register values are compared for each count clock, and an interrupt is generated by a match. If the CCLRCn bit of timer mode control register Cn1 (TMCCn1) is set to 1, the TMCn value is cleared to 0 at the same time as a match with the CCCn0 register (it is not cleared to 0 by a match with the CCCn1 register) (n = 0 to 5).

A compare register is equipped with a set/reset function. The corresponding timer output (TOCn) is set or reset, in synchronization with the generation of a match signal.

The interrupt selection source differs according to the function of the selected register.

- Cautions 1. To write to capture/compare registers Cn0 and Cn1, always set the CAECn bit to 1 first. If the CAECn bit is 0, the data that is written will be invalid.
  - 2. Write to capture/compare registers Cn0 and Cn1 after setting them as compare registers via TMCCn0 and TMCCn1 register settings. If they are set as capture registers (CMSCn0 and CMSCn1 bits of TMCCn1 register = 0), no data is written even if a write operation is performed to CCCm0 and CCCm1 (m = 0 to 3, n = 0 to 5).
  - 3. When these registers are set as compare registers, INTPCn0 and INTPCn1 cannot be used (n = 0 to 5).

When using these registers as an external interrupt input pin, use the INTP65 and INTP66 pins.

### 9.1.5 Control registers

## (1) Timer mode control registers C00 to C50 (TMCC00 to TMCC50)

The TMCCn0 registers control the operation of TMCn (n = 0 to 5). These registers can be read or written in 8-bit or 1-bit units. Be sure to clear bits 3 and 2 to 0. If they are set to 1, the operation is not guaranteed.

- Cautions 1. The CAECn and other bits cannot be set at the same time. The other bits and the registers of the other TMCn unit should always be set after the CAECn bit has been set. Also, to use external pins related to the timer function when timer C is used, be sure to set the CAECn bit to 1 after setting the external pins to control mode.
  - 2. When conflict occurs between an overflow and a TMCCn0 register write, the OVFCn bit value becomes the value written during the TMCCn0 register write (n = 0 to 5).

However, if TMCn is cleared to 0000H after a match at FFFFH when the CCCn0 register is set to compare mode (CMSCn0 bit of TMCCn1 register = 1) and clearing is enabled for a match when TMCn and CCCn0 are compared (CCLRCn bit of TMCCn1 register = 1), then TMCn is considered to be cleared and the OVFCn bit does not become 1. Also, no INTOVCn interrupt is generated.           The OVFCn bit retains the value 1 until 0 is written directly or until an asynchronous reset is performed because the CAECn bit is 0. An interrupt operation due to an overflow is independent of the OVFCn bit, and the interrupt request flag (OVCIFn) for INTOVCn is not affected even if the OVFCn bit is manipulated. If an overflow occurs while the OVFCn bit is being read, the flag value changes, and the change is reflected

(2) Timer mode control registers C01 to C51 (TMCC01 to TMCC51)

The TMCCn1 registers control the operation of TMCn (n = 0 to 5). These registers can be read or written in 8-bit units.

- Cautions 1. The various bits of the TMCCn1 register must not be changed during timer operation. If they are to be changed, they must be changed after setting the CECn bit of the TMCCn0 register to 0. If these bits are overwritten during timer operation, operation cannot be guaranteed (n = 0 to 5).
  - 2. If the ENTOCn and ALVCn bits are changed at the same time, a glitch (spike shaped noise) may be generated in the TOCn pin output. Either create a circuit configuration that will not malfunction even if a glitch is generated or make sure that the ENTOCn and ALVCn bits do not change at the same time (n = 0 to 5).
  - TOCn output is not changed by an external interrupt signal (INTPCm0 or INTPCm1). To use the TOCn signal, specify that the capture/compare registers are compare registers (CMSCn0 and CMSCn1 bits of TMCCn1 register = 1) (m = 0 to 3, n = 0 to 5).
  - 4. The TMCC41 and TMCC51 registers can be used only when the CCC40, CCC41, CCC50, and CCC51 registers are used as compare registers. They cannot be used when the CCC40, CCC41, CCC50, and CCC51 registers are used as capture registers.
  - 5. To clear the external interrupt signal by setting the ECLRCn bit, be sure to make the following setting.

Count clock period of TMD0 > Count clock period of TMCn

If this setting is not made, the falling edge of the INTCMD0 interrupt signal may not be detected.

Correct example (if count clock of TMD0 is slow) CSD02 to CSD00 bits of TMCD0 register = 011: fx/64 CSCn2 to CSCn0 bits of TMCC0 register = 001: fx/16

**Remark** Resetting the flip-flop of the TOCn output takes precedence (n = 0 to 5).

#### (3) Valid edge select registers C0 to C3 (SESC0 to SESC3)

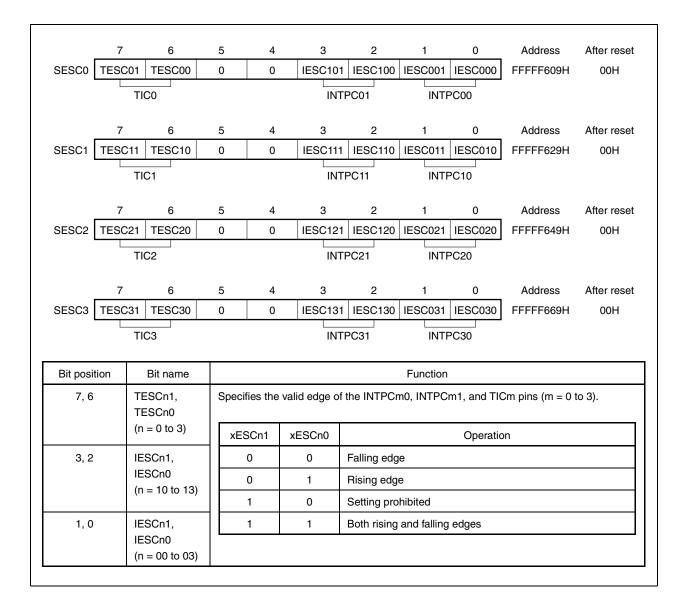

These registers specify the valid edge of an external interrupt request (INTPC00, INTPC01, INTPC10, INTPC11, INTPC20, INTPC21, INTPC30, INTPC31, and TIC0 to TIC3) from an external pin of TMCn (n = 0 to 3).

The rising edge, the falling edge, or both rising and falling edges can be specified as the valid edge independently for each pin.

Each of these registers can be read or written in 8-bit units.

Be sure to clear bits 5 and 4 to 0. If they are set to 1, the operation is not guaranteed.

- Cautions 1. The various bits of the SESCn register must not be changed during timer operation (n = 0 to 3). If they are to be changed, they must be changed after setting the CECn bit of the TMCCn0 register to 0. If the SESCn register is overwritten during timer operation, operation cannot be guaranteed.
  - 2. Even when using the INTPC00/TIC0, INTPC10/TIC1, INTPC20/TIC2, and INTPC30/TIC3 pins as INTPC00, INTPC10, INTPC20, and INTPC30, respectively, without using timer C, be sure to set the CAECn and CECn bits of timer mode control registers C00 to C03 (TMCC00 to TMCC30) to 1.
  - 3. Before setting the trigger mode of the INPTC00, INTPC01, INTPC10, INTPC11, INTPC20, INTPC21, INTPC30, INTPC31, and TIC0 to TIC3 pins, set the PMCx register (x = 5 to 7). Then set the CAECn and CECn bits of the TMCCn0 register to 1 (n = 0 to 3). If the PMCx register is set after the SESCn register has been set, an illegal interrupt, incorrect counting, and incorrect clearing may occur depending on the timing of setting the PMCx register (n = 0 to 3, x = 5 to 7).

## (4) Noise elimination width setting registers C0 to C3 (NCWC0 to NCWC3)

The NCWCn registers are used to set the noise elimination width of the digital noise filter of the timer C input pin (n = 0 to 3).

These registers can be read or written in 8-bit units.

Be sure to clear bits 7 to 2 to 0. If they are set to 1, the operation is not guaranteed.

#### 9.1.6 Operation

#### (1) Count operation

Timer C can function as a 16-bit free-running timer or as an external signal event counter. The setting for the type of operation is specified by timer mode control registers Cn0 and Cn1 (TMCCn0 and TMCCn1) (n = 0 to 5).

When it operates as a free-running timer, if the CCCn0 or CCCn1 register and the TMCn count value match, an interrupt signal is generated and the timer output signal (TOCn) can be set or reset. Also, a capture operation that holds the TMCm count value in the CCCm0 or CCCm1 register is performed, in synchronization with the valid edge that was detected from the external interrupt request input pin as an external trigger (m = 0 to 3). The capture value is held until the next capture trigger is generated.

# Caution When using the INTPCm0/TICm0 pin as TICm0 (external clock input pin), be sure to disable the INTPCm0 interrupt or set the CCCm0 register to compare mode (m = 0 to 3).

#### Figure 9-2. Basic Operation of Timer C

## (2) Overflow

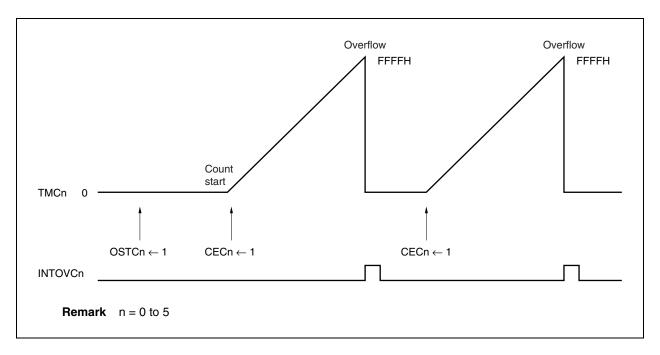

When the TMCn register has counted the count clock from FFFFH to 0000H, the OVFCn bit of the TMCCn0 register is set to 1, and an overflow interrupt (INTOVCn) is generated at the same time. However, if the CCCn0 register is set to compare mode (CMSCn0 bit = 1) and to the value FFFFH when match clearing is enabled (CCLRCn bit = 1), then the TMCn register is considered to be cleared and the OVFCn bit is not set to 1 when the TMCn register changes from FFFFH to 0000H. Also, the overflow interrupt (INTOVCn) is not generated.

When the TMCn register is changed from FFFFH to 0000H because the CECn bit changes from 1 to 0, the TMCn register is considered to be cleared, but the OVFCn bit is not set to 1 and no INTOVCn interrupt is generated.

Also, timer operation can be stopped after an overflow by setting the OSTCn bit of the TMCCn1 register to 1. When the timer is stopped due to an overflow, the count operation is not restarted until the CECn bit of the TMCCn0 register is set to 1.

Operation is not affected even if the CECn bit is set to 1 during a count operation.

Remark n = 0 to 5

#### (3) Capture operation

The TMCn register has two capture/compare registers. These are the CCCn0 register and the CCCn1 register. A capture operation or a compare operation is performed according to the settings of both the CMSCn1 and CMSCn0 bits of the TMCCn1 register. If the CMSCn1 and CMSCn0 bits of the TMCCn1 register are cleared to 0, the register operates as a capture register.

A capture operation that captures and holds the TMCm count value asynchronously relative to the count clock is performed in synchronization with an external trigger. The valid edge that is detected from an external interrupt request input pin (INTPCm0 or INTPCm1) is used as an external trigger (capture trigger). The TMCm count value during counting is captured and held in the capture register, in synchronization with that capture trigger signal. The capture register value is held until the next capture trigger is generated.

Also, an interrupt request (INTCCCm0 or INTCCCm1) is generated by INTPCm0 or INTPCm1 signal input. The valid edge of the capture trigger is set by valid edge select register Cm (SESCm).

If both the rising and falling edges are set as capture triggers, the input pulse width from an external source can be measured. Also, if only one of the edges is set as the capture trigger, the input pulse cycle can be measured.

**Remark** m = 0 to 3 n = 0 to 5

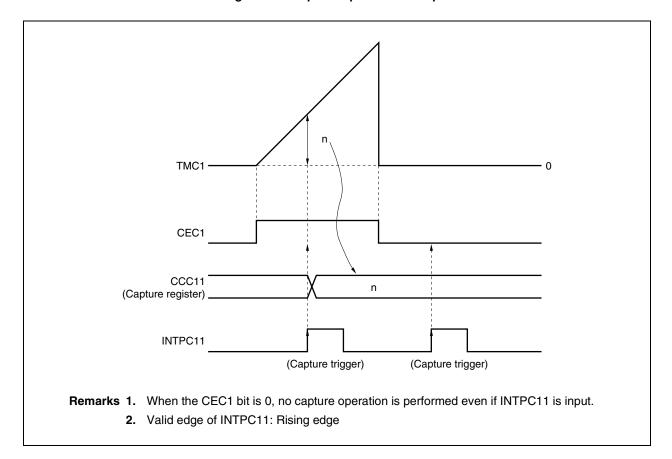

Figure 9-4. Capture Operation Example

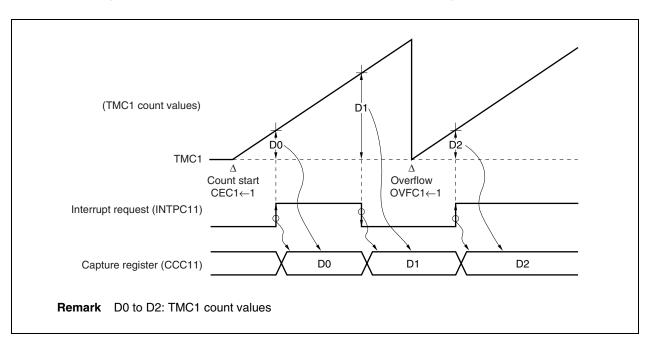

Figure 9-5. TMC1 Capture Operation Example (When Both Edges Are Specified)

#### (4) Compare operation

The TMCn register has two capture/compare registers. These are the CCCn0 register and the CCCn1 register. A capture operation or a compare operation is performed according to the settings of both the CMSCn1 and CMSCn0 bits of the TMCCn1 register. If the CMSCn1 and CMSCn0 bits of the TMCCn1 register are set to 1, the register operates as a compare register.

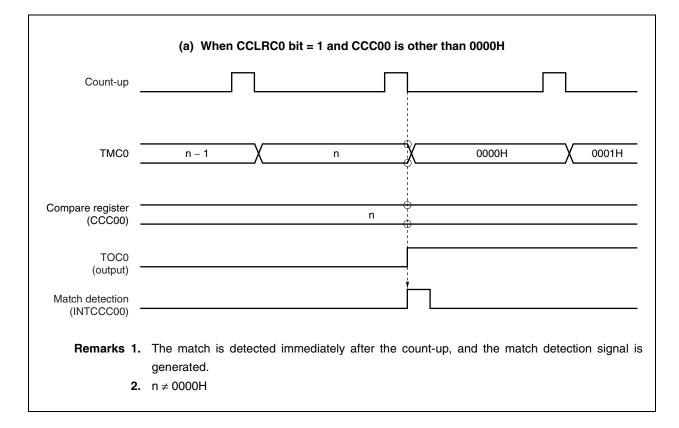

A compare operation that compares the value that was set in the compare register and the TMCn count value is performed.

If the TMCn count value matches the value of the compare register, which had been set in advance, a match signal is sent to the output controller. The match signal causes the timer output pin (TOCn) to change and an interrupt request signal (INTCCCn0 or INTCCCn1) to be generated at the same time.

If the CCCn0 or CCCn1 registers are cleared to 0000H, the 0000H after the TMCn register counts up from FFFFH to 0000H is judged as a match. In this case, the TMCn register value is cleared to 0 at the next count timing, however, this 0000H is not judged as a match. Also, the 0000H when the TMCn register begins counting is not judged as a match.

If match clearing is enabled (CCLRCn bit = 1) for the CCCn0 register, the TMCn register is cleared when a match with the TMCn register occurs during a compare operation.

#### Remark n = 0 to 5

#### Figure 9-6. Compare Operation Example (1/2)

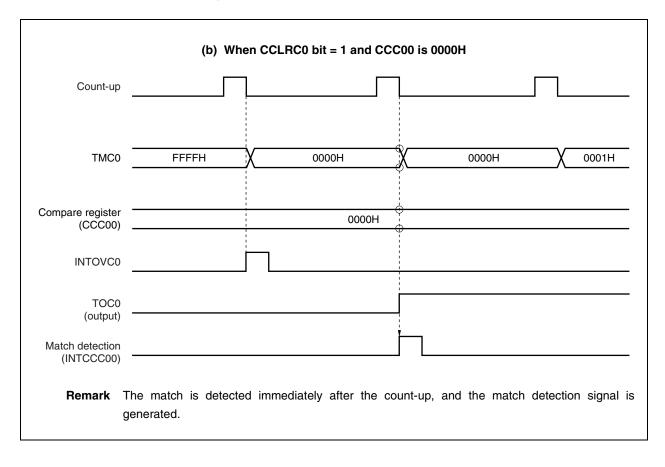

Figure 9-6. Compare Operation Example (2/2)

## (5) External pulse output

Timer C has six timer output pins (TOCn).

An external pulse output (TOCn) is generated when a match of the two compare registers (CCCn0 and CCCn1) and the TMCn register is detected.

If a match is detected when the TMCn count value and the CCCn0 value are compared, the output level of the TOCn pin is set. Also, if a match is detected when the TMCn count value and the CCCn1 value are compared, the output level of the TOCn pin is reset.

The output level of the TOCn pin can be specified by the TMCCn1 register.

Remark n = 0 to 5

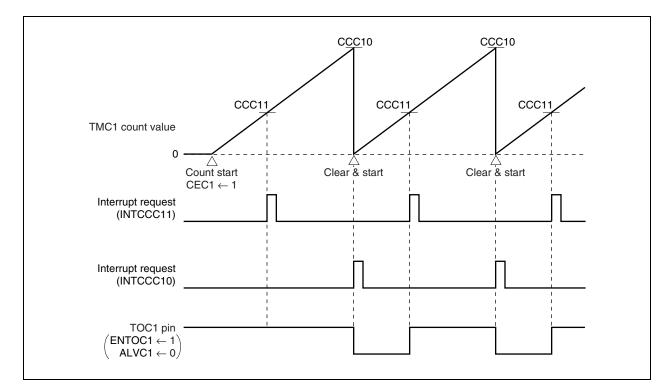

ENTOCn	ALVCn	TOCn Output							
		External Pulse Output	Output Level						
0	0	Disable	High level						
0	1	Disable	Low level						
1	0	Enable	When the CCCn0 register is matched: low level When the CCCn1 register is matched: high level						
1	1	Enable	When the CCCn0 register is matched: high level When the CCCn1 register is matched: low level						

**Remark** n = 0 to 5

#### 9.1.7 Application examples

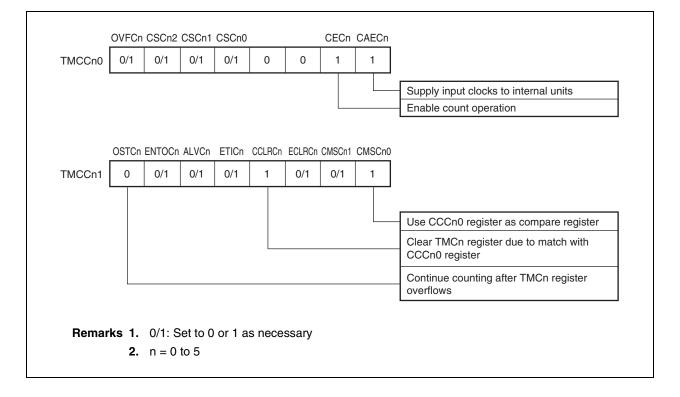

## (1) Interval timer

By setting the TMCCn0 and TMCCn1 registers as shown in Figure 9-8, timer C operates as an interval timer that repeatedly generates interrupt requests with the value that was preset in the CCCn0 register as the interval.

When the counter value of the TMCn register matches the setting value of the CCCn0 register, the TMCn register is cleared to 0000H and an interrupt request signal (INTCCCn0) is generated at the same time that the count operation resumes.

**Remark** n = 0 to 5

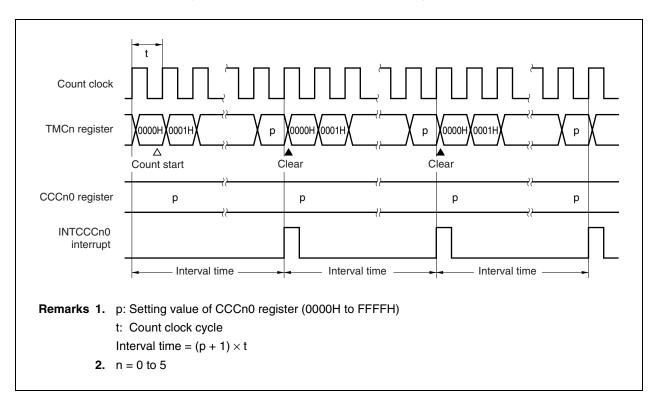

Figure 9-9. Interval Timer Operation Timing Example

#### (2) PWM output

By setting the TMCCn0 and TMCCn1 registers as shown in Figure 9-10, timer C can output a PWM signal, whose frequency is determined according to the setting of the CSCn2 to CSCn0 bits of the TMCCn0 register, with the values that were preset in the CCCn0 and CCCn1 registers determining the intervals.

When the counter value of the TMCn register matches the setting value of the CCCn0 register, the TOCn output becomes active. Then, when the counter value of the TMCn register matches the setting value of the CCCn1 register, the TOCn output becomes inactive. The TMCn register continues counting. When it overflows, its count value is cleared to 0000H, and the register continues counting. In this way, a PWM signal whose frequency is determined according to the setting of the CSCn2 to CSCn0 bits of the TMCCn0 register can be output. When the setting value of the CCCn0 register and the setting value of the CCCn1 register are the same, the TOCn output remains inactive and does not change.

The active level of the TOCn output can be set by the ALVCn bit of the TMCCn1 register.

Remark n = 0 to 5

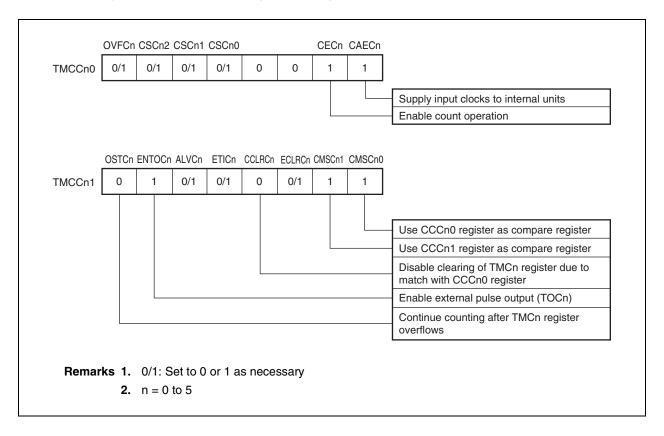

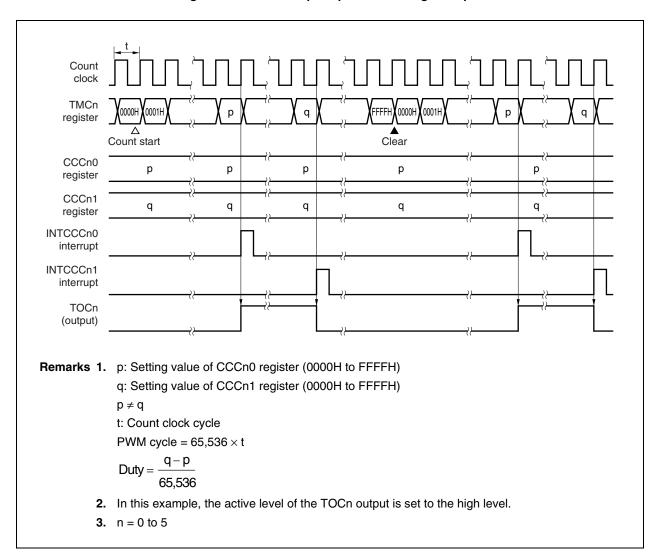

Figure 9-10. Contents of Register Settings When Timer C Is Used for PWM Output

#### (3) Cycle measurement

By setting the TMCCn0 and TMCCn1 registers as shown in Figure 9-12, timer C can measure the cycle of signals input to the INTPCm0 or INTPCm1 pin.

The valid edge of the INTPCm0 pin is selected according to the IESC0m1 and IESC0m0 bits of the SESCm register, and the valid edge of the INTPCm1 pin is selected according to the IESC1m1 and IESC1m0 bits of the SESCm register. Either the rising edge, the falling edge, or both edges can be selected as the valid edges of both pins.

If the CCCm0 register is set as a capture register, the valid edge input of the INTPCm0 pin is set as the trigger for capturing the TMCm register value in the CCCm0 register. When this value is captured, an INTCCCm0 interrupt is generated.

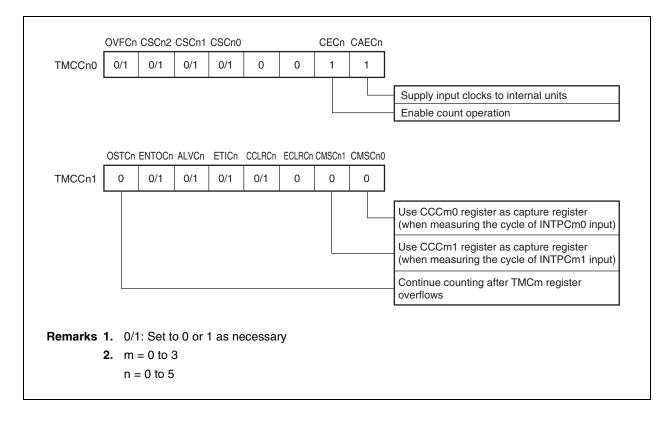

Similarly, if the CCCm1 register is set as a capture register, the valid edge input of the INTPCm1 pin is set as the trigger for capturing the TMCm register value in the CCCm1 register. When this value is captured, an INTCCCm1 interrupt is generated.

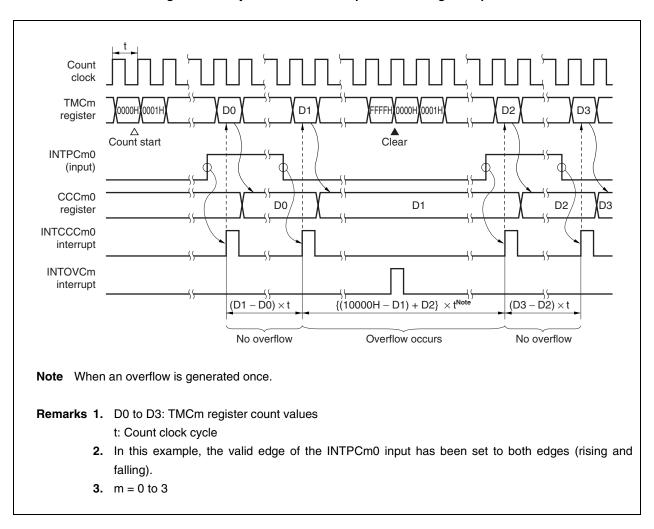

The cycle of signals input to the INTPCm0 pin is calculated by obtaining the difference between the TMCm register's count value (Dx) that was captured in the CCCm0 register according to the x-th valid edge input of the INTPCm0 pin and the TMCm register's count value (D(x+1)) that was captured in the CCCm0 register according to the (x+1)-th valid edge input of the INTPCm0 pin and multiplying the value of this difference by the cycle of the clock control signal.

The cycle of signals input to the INTPCm1 pin is calculated by obtaining the difference between the TMCm register's count value (Dx) that was captured in the CCCm1 register according to the x-th valid edge input of the INTPCm1 pin and the TMCm register's count value (D(x+1)) that was captured in the CCCm1 register according to the (x+1)-th valid edge input of the INTPCm1 pin and multiplying the value of this difference by the cycle of the clock control signal.

**Remark** m = 0 to 3 n = 0 to 5

## Figure 9-12. Contents of Register Settings When Timer C Is Used for Cycle Measurement

## 9.1.8 Cautions

Various cautions concerning timer C are shown below.

- (1) If a conflict occurs between the reading of the CCCm0 register and a capture operation when the CCCm0 register is used in capture mode, an external trigger (INTPCm0) valid edge is detected and an external interrupt request (INTCCCm0) is generated, however, the timer value is not stored in the CCCm0 register.
- (2) If a conflict occurs between the reading of the CCCm1 register and a capture operation when the CCCm1 register is used in capture mode, an external trigger (INTPCm1) valid edge is detected and an external interrupt request (INTCCCm1) is generated, however, the timer value is not stored in the CCCm1 register.
- (3) The following bits and registers must not be rewritten during operation (CECn = 1).
  - CSCn2 to CSCn0 bits of TMCCn0 register
  - TMCCn1 register
  - SESCm register
- (4) The CAECn bit of the TMCCn0 register is a TMCn reset signal. To use TMCn, first set the CAECn bit to 1.
- (5) The digital noise elimination time (0 to 5) × fx/4 are required to detect the valid edge of the external interrupt request signal (INTPCm0 or INTPCm1) or the external clock input (TICm). Therefore, edge detection will not be performed normally for changes that are less than the digital noise elimination time. For details of digital noise elimination, see 14.6.3 Timer C and timer ENC1 input pins.
- (6) The operation of an external interrupt request signal (INTCCCn0 or INTCCCn1) is automatically determined according to the operating state of the capture/compare register. When the capture/compare register is used for a capture operation, the external interrupt request signal is used for valid edge detection. When the capture/compare register is used for a compare operation, the external interrupt request signal is used for an interrupt request signal is used for an interrupt indicating a match with the TMCn register.
- (7) If the ENTOCn and ALVCn bits are changed at the same time, a glitch (spike shaped noise) may be generated in the TOCn pin output. Either create a circuit configuration that will not malfunction even if a glitch is generated or make sure that the ENTOCn and ALVCn bits are not changed at the same time.
- (8) Even when using the INTPC00/TIC0, INTPC10/TIC1, INTPC20/TIC2, and INTPC30/TIC3 pins as INTPC00, INTPC10, INTPC20, and INTPC30, respectively, without using timer C, be sure to set the CAECn and CECn bits of timer mode control registers C00 to C03 (TMCC00 to TMCC30) to 1.

#### 9.2.4 Timer D

#### (1) Timers D0 to D3 (TMD0 to TMD3)

TMDn is a 16-bit timer. It is mainly used as an interval timer for software (n = 0 to 3). Starting and stopping TMDn is controlled by the CEDn bit of the timer mode control register Dn (TMCDn) (n = 0 to 3).

Division by the prescaler can be selected for the count clock from among fx/8, fx/16, fx/32, fx/64, fx/128, fx/256, fx/512, and fx/1,024 by the CSDn0 to CSDn2 bits of the TMCDn register (fx: main clock). TMDn is read-only in 16-bit units.

TMD0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address FFFFF540H	After reset 0000H
TMD1																	FFFF550H	0000H
TMD2																	FFFF560H	0000H
TMD3																	FFFF570H	0000H

The conditions for which the TMDn register becomes 0000H are shown below (n = 0 to 3).

- Reset input
- CAEDn bit = 0
- CEDn bit = 0
- Match of TMDn register and CMDn register
- Overflow
  - Cautions 1. If the CAEDn bit of the TMCDn register is cleared to 0, a reset is performed asynchronously.
    - 2. If the CEDn bit of the TMCDn register is cleared to 0, a reset is performed, in synchronization with the internal clock. Similarly, a synchronized reset is performed after a match with the CMDn register and after an overflow.
    - 3. The count clock must not be changed during a timer operation. If it is to be overwritten, it should be overwritten after the CEDn bit is cleared to 0.
    - 4. Up to 8 clocks (1 cycle = 1/fx (fx: main clock)) are required after a value is set in the CEDn bit until the set value is transferred to internal units. When a count operation begins, the count cycle from 0000H to 0001H differs from subsequent cycles.
    - 5. After a compare match is generated, the timer is cleared at the next count clock. Therefore, if the division ratio is large, the timer value may not be zero even if the timer value is read immediately after a match interrupt is generated.
    - 6. To initialize the TMDn register and start counting again, set the CEDn bit of the TMCDn register to 1 after 8 clocks (1 cycle = 1/fx (fx: main clock)).

#### (2) Compare registers D0 to D3 (CMD0 to CMD3)

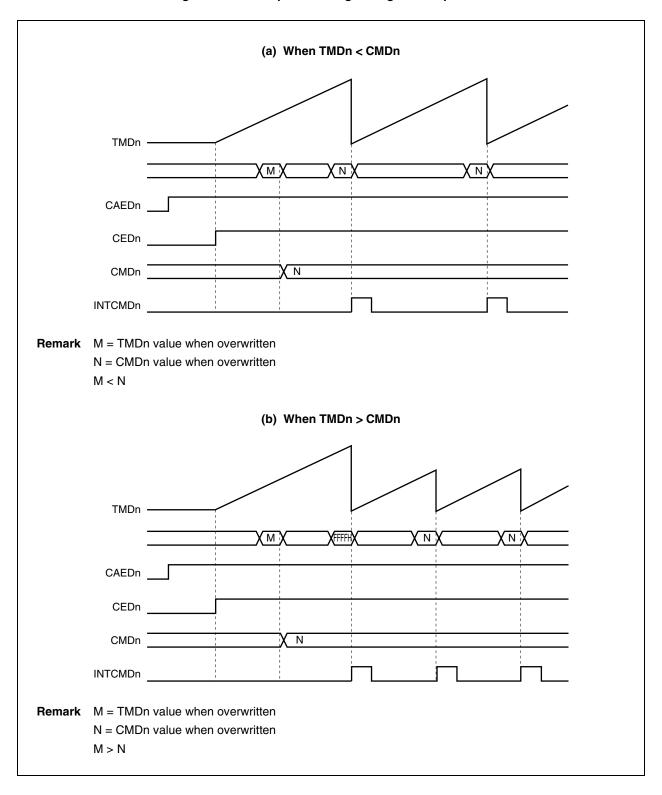

CMDn and the TMDn register count value are compared, and an interrupt request signal (INTCMDn) is generated when a match occurs. TMDn is cleared, in synchronization with this match. If the CAEDn bit of the TMCDn register is cleared to 0, a reset is performed asynchronously, and the registers are initialized (n = 0 to 3).

The CMDn registers are configured with a master/slave configuration. When a CMDn register is written, data is first written to the master register and then the master register data is transferred to the slave register. In a compare operation, the slave register value is compared with the count value of the TMDn register. When a CMDn register is read, data in the master side is read out.

CMDn can be read or written in 16-bit units.

- Cautions 1. A write operation to a CMDn register requires 8 clocks until the value that was set in the CMDn register is transferred to internal units. When writing continuously to the CMDn register, be sure to reserve a time interval of at least 8 clocks (1 cycle = 1/fx (fx: main clock)).
  - 2. The CMDn register can be overwritten only once in a single TMDn register cycle (from 0000H until an INTCMDn interrupt is generated due to a match of the TMDn register and CMDn register). If this cannot be secured by the application, make sure that the CMDn register is not overwritten during timer operation.
  - Note that an INTCMDn interrupt will be generated after an overflow if a value less than the counter value is written in the CMDn register during TMDn register operation (Figure 9-15).

#### 9.2.5 Control registers

#### (1) Timer mode control registers D0 to D3 (TMCD0 to TMCD3)

The TMCDn registers control the operation of timer Dn (n = 0 to 3). These registers can be read or written in 8-bit or 1-bit units.

Caution The CAEDn and other bits cannot be set at the same time. The other bits and the registers of the other TMDn units should always be set after the CAEDn bit has been set.

#### 9.2.6 Operation

#### (1) Compare operation

TMDn can be used for a compare operation in which the value that was set in a compare register (CMDn) is compared with the TMDn count value (n = 0 to 3).

If a match is detected by the compare operation, an interrupt (INTCMDn) is generated. The generation of the interrupt causes TMDn to be cleared to 0 at the next count timing. This function enables timer D to be used as an interval timer.

CMDn can also be cleared to 0. In this case, when an overflow occurs and TMDn becomes 0, a match is detected and INTCMDn is generated. Although the TMDn value is cleared to 0 at the next count timing, INTCMDn is not generated by this match.

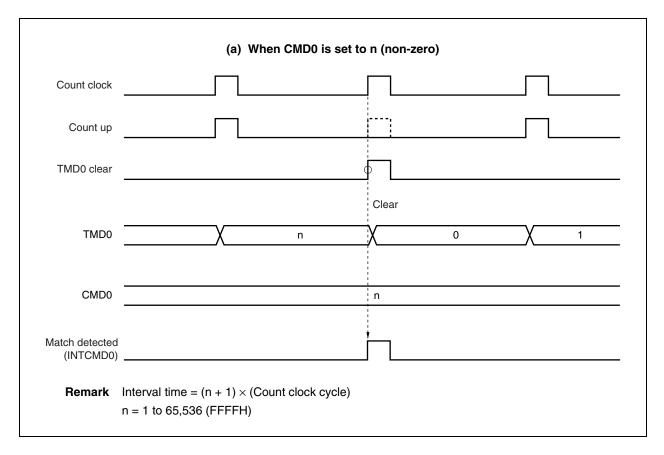

Figure 9-16. TMD0 Compare Operation Example (1/2)

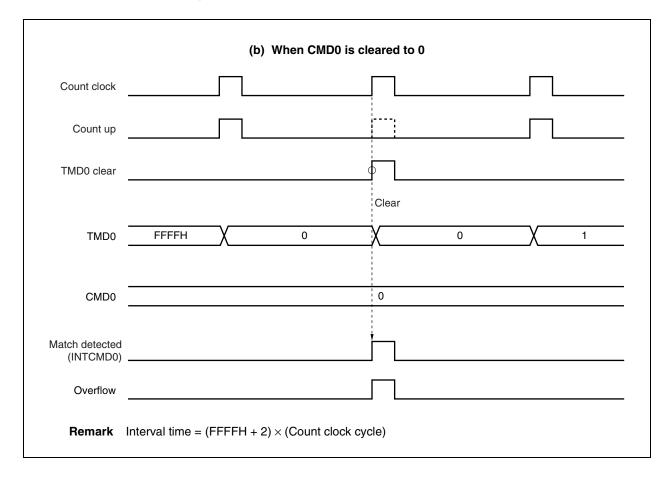

Figure 9-16. TMD0 Compare Operation Example (2/2)

#### 9.2.7 Application examples

#### (1) Interval timer

This section explains an example in which timer D is used as an interval timer with 16-bit precision. Interrupt requests (INTCMDn) are output at equal intervals (see **Figure 9-16 TMD0 Compare Operation Example**). The setup procedure is shown below (n = 0 to 3).

- <1> Set the CAEDn bit to 1.
- <2> Set each register.
  - Select the count clock using the CSDn0 to CSDn2 bits of the TMCDn register.
  - Set the compare value in the CMDn register.
- <3> Start counting by setting the CEDn bit to 1.
- <4> If the TMDn register and CMDn register values match, an INTCMDn interrupt is generated.
- <5> INTCMDn interrupts are generated thereafter at equal intervals.

**Remark** n = 0 to 3

#### 9.2.8 Cautions

Various cautions concerning timer D are shown below.

- (1) To operate TMDn, first set the CAEDn bit to 1.
- (2) Up to 8 clocks are required after a value is set in the CEDn bit until the set value is transferred to internal units. When a count operation begins, the count cycle from 0000H to 0001H differs from subsequent cycles (1 cycle = 1/fx (fx: main clock)).
- (3) To initialize the TMDn register status and start counting again, clear the CEDn bit to 0 and then set the CEDn bit to 1 after an interval of 8 clocks has elapsed.
- (4) Up to 8 clocks are required until the value that was set in the CMDn register is transferred to internal units. When writing continuously to the CMDn register, be sure to secure a time interval of at least 8 clocks (1 cycle = 1/fx (fx: main clock)).
- (5) The CMDn register can be overwritten only once during a timer/counter operation (from 0000H until an INTCMDn interrupt is generated due to a match of the TMDn register and CMDn register). If this cannot be secured, make sure that the CMDn register is not overwritten during a timer/counter operation.
- (6) The count clock must not be changed during a timer operation. If it is to be overwritten, it should be overwritten after the CEDn bit is cleared to 0. If the count clock is overwritten during a timer operation, operation cannot be guaranteed.
- (7) A match signal will be generated after an overflow if a value less than the counter value is written in the CMDn register during TMDn register operation.

**Remark** n = 0 to 3

#### 9.3 Timer ENC1

#### 9.3.1 Features

Timers ENC10 and ENC11 (TMENC10, TMENC11) are 16-bit up/down counters that perform the following operations.

- General-purpose timer mode Free-running timer
   PWM output
- Up/down counter mode
   UDC mode A
   UDC mode B

#### 9.3.2 Function overview

- 16-bit 2-phase encoder input up/down counter & general-purpose timer (TMENC10, TMENC11): 2 channels
- Compare registers: 4
- Capture/compare registers: 4
- Interrupt request sources
  - Capture/compare match interrupt: 4 sources
  - Compare match interrupt request: 4 sources
- Capture request signal: 4 sources
  - The TMENC1n value can be latched using the valid edge of the INTP1n0 and INTP1n1 pins corresponding to the capture/compare register as the capture trigger.
- Count clock selectable through division by prescaler
- Timer/counter count clock sources: 2 types
  - (selection of external pulse input or main clock division)
- 2-phase encoder input

The 2-phase external encoder signal is used as the count clock of the timer/counter via the external clock input pins (TIUD1n, TCUD1n). The counter mode can be selected from among the four following modes.

• Mode 1: Counts the input pulses of the count pulse input pin.

Up/down is specified by the level of the other input pin.

- Mode 2: Counts up/down using the respective input pulses of the up count pulse input pin and down count pulse input pin.
- Mode 3: Counts up/down using the phase relationship of the pulses input to the 2 pins.
- Mode 4: Counts up/down using the phase relationship of the pulses input to the 2 pins. Counting is done using the respective rising edges and the falling edges of the pulses.
- PWM output function

In the general-purpose timer mode, 16-bit resolution PWM can be output from the TO1n pin.

#### • Timer clear

The following timer clear operations are performed according to the mode that is used.

- (a) General-purpose timer mode: Timer clear operation is possible upon occurrence of match with CM1n0 set value.
- (b) Up/down counter mode: The timer clear operation can be selected from among the following four conditions.
  - (i) Timer clear performed upon occurrence of match with CM1n0 set value during TMENC1n up count operation, and timer clear performed upon occurrence of match with CM1n1 set value during TMENC1n down count operation.
  - (ii) Timer clear performed only by external input.
  - (iii) Timer clear performed upon occurrence of match between TMENC1n count value and CM1n0 set value.
  - (iv) Timer clear performed upon occurrence of external input and match between TMENC1n count value and CM1n0 set value.
- External pulse output (TO1n): 2

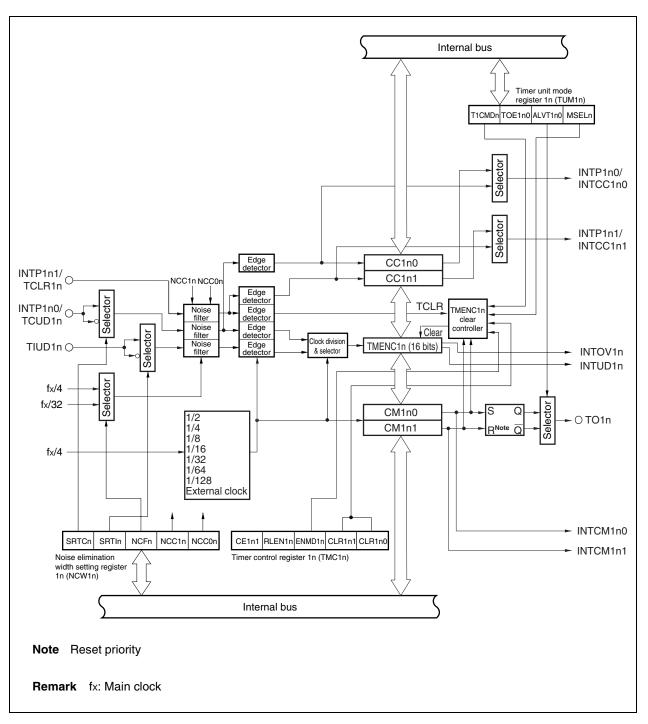

Figure 9-17. Timer ENC1 Block Diagram

#### 9.3.4 Timer ENC1

#### (1) Timers ENC10, ENC11 (TMENC10, TMENC11)

TMENC1n is a 2-phase encoder input up/down counter and general-purpose timer. It can be read or written in 16-bit units.

- Cautions 1. Writing to TMENC1n is enabled only when the CE1n1 bit of the TMC1n register is 0 (count operation disabled).
  - 2. It is prohibited to set the T1CMDn bit (general-purpose timer mode) and the MSELn bit (UDC mode B) of the TUM1n register to 0 and 1, respectively.
  - 3. Continuous reading of TMENC1n is prohibited. If TMENC1n is continuously read, the second read value may differ from the actual value. If TMENC1n must be read twice, be sure to read another register between the first and the second read operation.
  - 4. Writing the same value to the TMENC1n, CC1n0, and CC1n1 registers, and the STATUS1n register is prohibited. Writing the same value to the CCR1n, TUM1n, TMC1n, SESA1n, and PRM1n registers, and CM1n0 and CM1n1 registers is permitted (writing the same value is guaranteed even during a count operation).

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
TMENC10																	FFFFF5A0H	0000H
TMENC11																	FFFF5D0H	0000H

TMENC1n start and stop is controlled by the CE1n1 bit of timer control register 1n (TMC1n). The TMENC1n operation consists of the following two modes.

#### (a) General-purpose timer mode

In the general-purpose timer mode, TMENC1n operates as a 16-bit interval timer, free-running timer, or PWM output.

Counting is performed based on the clock selected by software.

Division by the prescaler can be selected for the count clock from among fx/8, fx/16, fx/32, fx/64, fx/128, fx/256, or fx/512 using the PRM1n2 to PRM1n0 bits of prescaler mode register 1n (PRM1n) (fx: main clock).

#### (b) Up/down counter mode (UDC mode)

In the UDC mode, TMENC1n functions as a 16-bit up/down counter that performs counting based on the TCUD1n and TIUD1n input signals.

Two operation modes can be set by the MSELn bit of the TUM1n register for this mode.

#### (i) UDC mode A (when T1CMDn bit = 1, MSELn bit = 0)

TMENC1n can be cleared by setting the CLR1n1 and CLR1n0 bits of the TMC1n register.

#### (ii) UDC mode B (when T1CMDn bit = 1, MSELn bit = 1)

TMENC1n is cleared upon a match with CM1n0 during a TMENC1n up count operation. TMENC1n is cleared upon a match with CM1n1 during a TMENC1n down count operation.

When the CE1n1 bit of the TMC1n register is 1, TMENC1n counts up when the operation mode is the general-purpose mode, and counts up/down when the operation mode is the UDC mode.

- Cautions 1. The TCUD1n and INTP1n0 pins function alternately. Therefore, because the TCUD1n pin is used in the UDC mode, the external capture function of the INTP1n0 pin cannot be used.
  - 2. The TCLR1n and INTP1n1 pins function alternately. Therefore, when the TCLR1n input is used in UDC mode A, the external capture function of the INTP1n1 pin cannot be used.

The conditions for clearing TMENC1n are as follows, depending on the operation mode.

Operation Mode	TUM1n	Register	TM	IC1n Regi	ster	TMENC1n Clear
	T1CMDn Bit	MSELn Bit	ENMD1n Bit	CLR1n1 Bit	CLR1n0 Bit	
General-purpose	0	0	0	×	×	Clearing not performed
timer mode			1	×	×	Cleared upon match with CM1n0 set value
UDC mode A	1	0	×	0	0	Cleared only by TCLR1n input
			×	0	1	Cleared upon match with CM1n0 set value during up count operation
			×	1	0	Cleared by TCLR1n input or upon match with CM1n0 set value during up count operation
			×	1	1	Clearing not performed
UDC mode B	1	1	×	×	×	Cleared upon match with CM1n0 set value during up count operation or upon match with CM1n1 set value during down count operation

**Remark** ×: Indicates that the set value of that bit is ignored.

#### (2) Compare registers 100, 110 (CM100, CM110)

CM1n0 is a 16-bit register that always compares its value with the value of TMENC1n. When the value of a compare register matches the value of TMENC1n, an interrupt signal is generated. The interrupt generation timing in the various modes is described below.

- In the general-purpose timer mode (T1CMDn bit of TUM1n register = 0) and UDC mode A (MSELn bit of TUM1n register = 0), an interrupt signal (INTCM1n0) is always generated upon occurrence of a match.
- In UDC mode B (MSELn bit of TUM1n register = 1), an interrupt signal (INTCM1n0) is generated only upon occurrence of a match during an up count operation.

CM1n0 can be read or written in 16-bit units.

## Caution When the CE1n1 bit of the TMC1n register is 1, it is prohibited to overwrite the value of the CM1n0 register.

CM100	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address FFFFF5A2H	After reset 0000H
CM110																	FFFF5D2H	0000H

#### (3) Compare registers 101, 111 (CM101, CM111)

CM1n1 is a 16-bit register that always compares its value with the value of TMENC1n. When the value of the compare register matches the value of TMENC1n, an interrupt signal is generated. The interrupt generation timing in the various modes is described below.

- In the general-purpose timer mode (T1CMDn bit of TUM1n register = 0) and UDC mode A (MSELn bit of TUM1n register = 0), an interrupt signal (INTCM1n1) is always generated upon occurrence of a match.
- In UDC mode B (MSELn bit of TUM1n register = 1), an interrupt signal (INTCM1n1) is generated only upon occurrence of a match during a down count operation.

CM1n1 can be read or written in 16-bit units.

## Caution When the CE1n1 bit of the TMC1n register is 1, it is prohibited to overwrite the value of the CM1n1 register.

CM101	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address FFFFF5A4H	After reset 0000H

#### (4) Capture/compare registers 100, 110 (CC100, CC110)

CC1n0 is a 16-bit register. It can be specified as a capture register or as a compare register using capture/compare control register 1n (CCR1n). CC1n0 can be read or written in 16-bit units.

## Cautions 1. When used as a capture register (CMSn0 bit of CCR1n register = 0), write access from the CPU is prohibited.

- 2. When used as a compare register (CMSn0 bit of CCR1n register = 1) and the CE1n1 bit of the TMC1n register is 1, overwriting the CC1n0 register values is prohibited.
- 3. When the CE1n1 bit of the TMC1n register is 0, the capture trigger is disabled.
- 4. When the operation mode is changed from capture register to compare register, set a new compare value.
- 5. Continuous reading of CC1n0 is prohibited. If CC1n0 is continuously read, the second read value may differ from the actual value. If CC1n0 must be read twice, be sure to read another register between the first and the second read operation.

CC100	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address FFFFF5A6H	After reset 0000H
CC110																	FFFF5D6H	0000H

#### (a) When set as a capture register

When CC1n0 is set as a capture register, the valid edge of the corresponding external interrupt INTP1n0 signal is detected as the capture trigger. TMENC1n latches the count value in synchronization with the capture trigger (capture operation). The latched value is held in the capture register until the next capture operation.

The valid edge of external interrupts (rising edge, falling edge, both edges) is selected by valid edge select register 1n (SESA1n).

When the CC1n0 register is specified as a capture register, interrupts are generated upon detection of the valid edge of the INTP1n0 signal.

## Caution The TCUD1n and INTP1n0 pins function alternately. Therefore, because the TCUD1n pin is used in the UDC mode, the external capture function of the INTP1n0 pin cannot be used.

#### (b) When set as a compare register

When CC1n0 is set as a compare register, it always compares its own value with the value of TMENC1n. If the value of CC1n0 matches the value of the TMENC1n, CC1n0 generates an interrupt signal (INTCC1n0).

#### (5) Capture/compare registers 101, 111 (CC101, CC111)

CC1n1 is a 16-bit register. It can be specified as a capture register or as a compare register using capture/compare control register 1n (CCR1n). CC1n1 can be read or written in 16-bit units.

## Cautions 1. When used as a capture register (CMSn1 bit of CCR1n register = 0), write access from the CPU is prohibited.

- 2. When used as a compare register (CMSn1 bit of CCR1n register = 1) and the CE1n1 bit of the TMC1n register is 1, overwriting the CC1n1 register values is prohibited.
- 3. When the CE1n1 bit of the TMC1n register is 0, the capture trigger is disabled.
- 4. When the operation mode is changed from capture register to compare register, newly set a compare value.
- 5. Continuous reading of CC1n1 is prohibited. If CC1n1 is continuously read, the second read value may differ from the actual value. If CC1n1 must be read twice, be sure to read another register between the first and the second read operation.

CC101	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address FFFF5A8H	After reset 0000H
CC111																	FFFF5D8H	0000H

#### (a) When set as a capture register

When CC1n1 is set as a capture register, the valid edge of the corresponding external interrupt INTP1n1 signal is detected as the capture trigger. TMENC1n latches the count value in synchronization with the capture trigger (capture operation). The latched value is held in the capture register until the next capture operation.

The valid edge of external interrupts (rising edge, falling edge, both edges) is selected by valid edge select register 1n (SESA1n).

When the CC1n1 register is specified as a capture register, interrupts are generated upon detection of the valid edge of the INTP1n1 signal.

# Caution The TCLR1n and INTP1n1 pins function alternately. Therefore, when the TCLR1n input is used in UDC mode A, the external capture function of the INTP1n1 pin cannot be used.

#### (b) When set as a compare register

When CC1n1 is set as a compare register, it always compares its own value with the value of TMENC1n. If the value of CC1n1 matches the value of the TMENC1n, CC1n1 generates an interrupt signal (INTCC1n1).

#### 9.3.5 Control registers

#### (1) Timer unit mode registers 10, 11 (TUM10, TUM11)

The TUM1n register is an 8-bit register used to specify the TMENC1n operation mode or to control the operation of the PWM output pin.

TUM1n can be read or written in 8-bit or 1-bit units.

## Cautions 1. Changing the value of the TUM1n register during TMENC1n operation (CE1n1 bit of TMC1n register = 1) is prohibited.

2. When the T1CMDn bit = 0 (general-purpose timer mode), setting MSELn bit = 1 (UDC mode B) is prohibited.

#### (2) Timer control registers 10, 11 (TMC10, TMC11)

The TMC1n register is used to enable/disable TMENC1n operation and to set transfer and timer clear operations.

TMC1n can be read or written in 8-bit or 1-bit units.

## Caution Changing the values of the TMC1n register bits other than the CE1n1 bit during TMENC1n operation (CE1n1 bit = 1) is prohibited.

#### (3) Capture/compare control registers 10, 11 (CCR10, CCR11)

The CCR1n register specifies the operation mode of the capture/compare registers (CC1n0, CC1n1). CCR1n can be read or written in 8-bit or 1-bit units.

Cautions 1. Overwriting the CCR1n register during TMENC1n operation (CE1n1 bit = 1) is prohibited.

- 2. The TCUD1n and INTP1n0 pins function alternately. Therefore, because the TCUD1n pin is used in the UDC mode, the external capture function of the INTP1n0 pin cannot be used.
- 3. The TCLR1n and INTP1n1 pins function alternately. Therefore, when the TCLR1n input is used in UDC mode A, the external capture function of the INTP1n1 pin cannot be used.

#### (4) Valid edge select registers 10, 11 (SESA10, SESA11)

The SESA1n register is used to specify the valid edge of external interrupt requests from external pins (INTP100, INTP101, INTP110, INTP111, TIUD10, TIUD11, TCUD10, TCUD11, TCLR10, TCLR11).

The valid edge (rising edge, falling edge, or both rising and falling edges) can be specified independently for each pin.

SESA1n can be read or written in 8-bit or 1-bit units.

- Cautions 1. Changing the values of the SESA1n register bits during TMENC1n operation (CE1n1 bit = 1) is prohibited.
  - 2. Before setting the trigger mode of the INTP100, INTP101, INTP110, INTP111, TIUD10, TIUD11, TCUD10, TCUD11, TCLR10, and TCLR11 pins, set the PMCDH register. If the PMCDH register is set after the SESA1n register has been set, an illegal interrupt, incorrect counting, and incorrect clearing may occur depending on the timing of setting the PMCDH register.

#### (5) Prescaler mode registers 10, 11 (PRM10, PRM11)

The PRM1n register is used to perform the following selections.

- Selection of count clock in general-purpose timer mode (T1CMDn bit of TUM1n register = 0)
- Selection of count operation mode in UDC mode (T1CMDn bit = 1)

PRM1n can be read or written in 8-bit or 1-bit units.

- Cautions 1. Overwriting the PRM1n register during TMENC1n operation (CE1n1 bit = 1) is prohibited.
  - 2. When the T1CMDn bit of the TUM1n register = 1 (UDC mode), setting the values of the PRM1n2 to PRM1n0 to 000, 001, 010, and 011 bits is prohibited.
  - 3. When TMENC1n is in mode 4, specification of the valid edge for the TIUD1n and TCUD1n pins is invalid.

### (a) In general-purpose timer mode (T1CMDn bit of TUM1n register = 0)

The count clock is fixed to the internal clock. The clock rate of TMENC1n is specified by bits PRM1n2 to PRM1n0.

#### (b) UDC mode (T1CMDn bit of TUM1n register = 1)

The TMENC1n count triggers in the UDC mode are as follows.

Operation Mode	TMENC1n Operation
Mode 1	Down count when TCUD1n = high level Up count when TCUD1n = low level
Mode 2	Up count upon detection of valid edge of TIUD1n input Down count upon detection of valid edge of TCUD1n input

#### (6) Status registers 10, 11 (STATUS10, STATUS11)

The STATUS1n register indicates the operating status of TMENC1n. STATUS1n is read-only in 8-bit or 1-bit units.

Remark n = 0, 1

Caution Overwriting the STATUS1n register during TMENC1n operation (CE1n1 bit = 1) is prohibited.

#### (7) Noise elimination width setting registers 10, 11 (NCW10, NCW11)

The NCW1n register is used to set the noise elimination width of the digital noise filter of the timer ENC1 input pin.

NCW1n can be read or written in 8-bit units.

- Cautions 1. Whether the signal is input through or inverted can be specified for each of the INTP1n0/TCUD1n and TIUD1n pins. The setting of the noise elimination width by the NCFn, NCC1n, and NCC0n bits is for each timer and cannot be changed for each pin.
  - 2. The setting of the SRTCn bit is valid even when the INTP1n0/TCUD1n pin is used as a capture trigger (INTP1n0).

#### 9.3.6 Operation

#### (1) Basic operation

The following two operation modes can be selected for TMENC1n.

#### (a) General-purpose timer mode (T1CMDn bit of TUM1n register = 0)

In the general-purpose timer mode, TMENC1n operates either as a 16-bit interval timer or as a PWM output timer (count operation is up count only).

The count clock to TMENC1n is selected by prescaler mode register 1n (PRM1n) (n = 0, 1).

#### (b) Up/down counter mode (UDC mode) (T1CMDn bit of TUM1n register = 1)

In the UDC mode, TMENC1n operates as a 16-bit up/down counter.

The external clock input (TIUD1n, TCUD1n pins) by PRM1n register setting is used as the TMENC1n count clock.

The UDC mode is further divided into two modes according to the TMENC1n clear conditions.

#### • UDC mode A (TUM1n register's T1CMDn bit = 1, MSELn bit = 0)

The TMENC1n clear source can be selected as only external clear input (TCLR1n), a match signal between the TMENC1n count value and the CM1n0 set value during up count operation, or the logical sum (OR) of the two signals, using bits CLR1n1 and CLR1n0 of the TMC1n register. TMENC1n can transfer the value of CM1n0 upon occurrence of a TMENC1n underflow.

#### • UDC mode B (TUM1n register's T1CMDn bit = 1, MSELn bit = 1)

The status of TMENC1n after a match of the TMENC1n count value and CM1n0 set value is as follows.

- <1> In the case of an up count operation, TMENC1n is cleared to 0000H, and the INTCM1n0 interrupt is generated.
- <2> In the case of a down count operation, the TMENC1n count value is decremented (-1).

The status of TMENC1n after a match of the TMENC1n count value and CM1n1 set value is as follows.

- <1> In the case of an up count operation, the TMENC1n count value is incremented (+1).
- <2> In the case of a down count operation, TMENC1n is cleared to 0000H, and the INTCM1n1 interrupt is generated.

#### (2) Operation in general-purpose timer mode

TMENC1n can perform the following operations in the general-purpose timer mode.

#### (a) Interval operation

TMENC1n and CM1n0 always compare their values and the INTCM1n0 interrupt is generated upon occurrence of a match.

TMENC1n is cleared to 0000H at the count clock following the match.

Furthermore, when one more count clock is input, TMENC1n counts up to 0001H. The interval time can be calculated with the following formula.

Interval time = (CM1n0 value + 1) × TMENC1n count clock rate

Caution Interval operation can be achieved by setting the ENMD1n bit of the TMC1n register to 1.

#### (b) Free-running operation

TMENC1n performs a full count operation from 0000H to FFFFH, and after the OVF1n bit of the STATUS1n register is set to 1, TMENC1n is cleared and resumes counting. The free-running cycle can be calculated by the following formula.

Free-running cycle =  $65,536 \times TMENC1n$  count clock rate

## Caution The free-running operation can be achieved by setting the ENMD1n bit of the TMC1n register to 0.

#### (c) Compare function

TMENC1n connects two compare register (CM1n0, CM1n1) channels and two capture/compare register (CC1n0, CC1n1) channels.

When the TMENC1n count value and the set value of one of the compare registers match, a match interrupt (INTCM1n0, INTCM1n1, INTCC1n0<sup>Note</sup>, INTCC1n1<sup>Note</sup>) is output.

Particularly in the case of interval operation, TMENC1n is cleared upon generation of the INTCM1n0 interrupt.

Note This match interrupt is generated when CC1n0 and CC1n1 are set to the compare register mode.

#### (d) Capture function

TMENC1n connects two capture/compare register (CC1n0, CC1n1) channels.

When CC1n0 and CC1n1 are set to the capture register mode, the value of TMENC1n is captured in synchronization with the corresponding capture trigger signal.

Furthermore, an interrupt request (INTCC1n0, INTCC1n1) is generated by the INTP1n0, INTP1n1 input signals.

Table 9-7.	Capture Trigge	r Signal (TMENC1n	n) to 16-Bit Capture Register
		· • • • • • • • • • • • • • • • • • • •	.,

Capture Register	Capture Trigger Signal
CC1n0	INTP1n0
CC1n1	INTP1n1

**Remark** CC1n0 and CC1n1 are capture/compare registers. Which of these registers is used is specified by capture/compare control register 1n (CCR1n).

The valid edge of the capture trigger is specified by valid edge select register 1n (SESA1n). If both the rising edge and the falling edge are selected as the capture triggers, it is possible to measure the input pulse width externally. If a single edge is selected as the capture trigger, the input pulse cycle can be measured.

#### (e) PWM output operation

PWM output operation is performed from the TO1n pin by setting TMENC1n to the general-purpose timer mode (T1CMDn bit = 0) using timer unit mode register 1n (TUM1n).

The resolution is 16 bits, and the count clock can be selected from among seven internal clocks (fx/8, fx/16, fx/32, fx/64, fx/128, fx/256, fx/512).

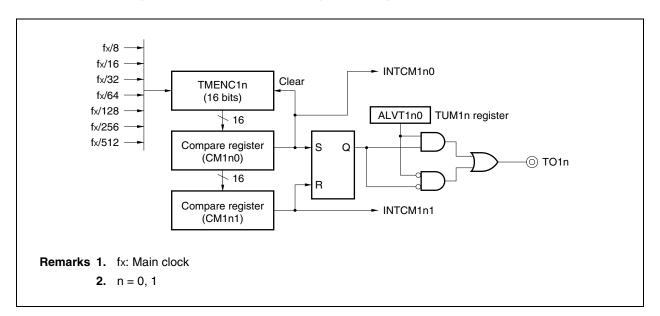

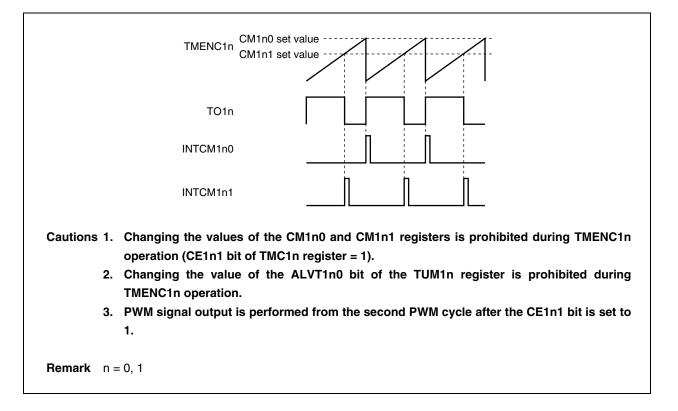

Figure 9-18. TMENC1n Block Diagram (During PWM Output Operation)

#### (i) Description of operation

The CM1n0 register is a compare register used to set the PWM output cycle. When the value of this register matches the value of TMENC1n, the INTCM1n0 interrupt is generated. The compare match is saved by hardware, and TMENC1n is cleared at the next count clock after the match.

The CM1n1 register is a compare register used to set the PWM output duty. Set the duty required for the PWM cycle.

#### (3) Operation in UDC mode

#### (a) Overview of operation in UDC mode

The count clock input to TMENC1n in the UDC mode (T1CMDn bit of TUM1n register = 1) can only be externally input from the TIUD1n and TCUD1n pins. Up/down count judgment in the UDC mode is determined based on the phase difference of the TIUD1n and TCUD1n pin inputs according to the PRM1n register setting (there is a total of four choices).

PF	RM1n Regist	ter	Operation	TMENC1n Operation
PRM1n2	PRM1n1	PRM1n0	Mode	
1	0	0	Mode 1	Down count when TCUD1n = high level Up count when TCUD1n = low level
1	0	1	Mode 2	Up count upon detection of valid edge of TIUD1n input Down count upon detection of valid edge of TCUD1n input
1	1	0	Mode 3	Automatic judgment in TCUD1n input level upon detection of valid edge of TIUD1n input
1	1	1	Mode 4	Automatic judgment upon detection of both edges of TIUD1n input and both edges of TCUD1n input

#### **Remark** n = 0, 1

The UDC mode is further divided into two modes according to the TMENC1n clear conditions (a count operation is performed only with TIUD1n and TCUD1n input in both modes).

#### • UDC mode A (TUM1n register's T1CMDn bit = 1, MSELn bit = 0)

The TMENC1n clear source can be selected as only external clear input (TCLR1n), a match signal between the TMENC1n count value and the CM1n0 set value during up count operation, or the logical sum (OR) of the two signals, using bits CLR1n1 and CLR1n0 of the TMC1n register. TMENC1n can transfer the value of CM1n0 upon occurrence of a TMENC1n underflow.

#### • UDC mode B (TUM1n register's T1CMDn bit = 1, MSELn bit = 1)

The status of TMENC1n after a match of the TMENC1n count value and CM1n0 set value is as follows.

- <1> In the case of an up count operation, TMENC1n is cleared to 0000H, and the INTCM1n0 interrupt is generated.
- <2> In the case of a down count operation, the TMENC1n count value is decremented (-1).

The status of TMENC1n after a match of the TMENC1n count value and CM1n1 set value is as follows.

- <1> In the case of an up count operation, the TMENC1n count value is incremented (+1).
- <2> In the case of a down count operation, TMENC1n is cleared to 0000H, and the INTCM1n1 interrupt is generated.

#### (b) Up/down count operation in UDC mode

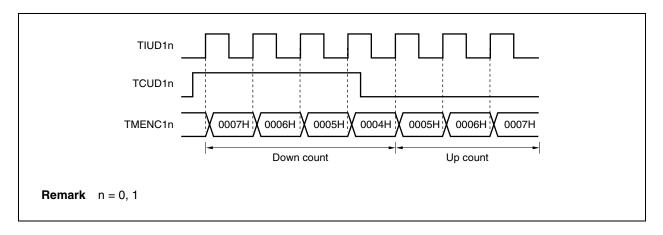

TMENC1n up/down count judgment in the UDC mode is determined based on the phase difference of the TIUD1n and TCUD1n pin inputs according to the PRM1n register setting.

#### (i) Mode 1 (PRM1n2 bit = 1, PRM1n1 bit = 0, PRM1n0 bit = 0)

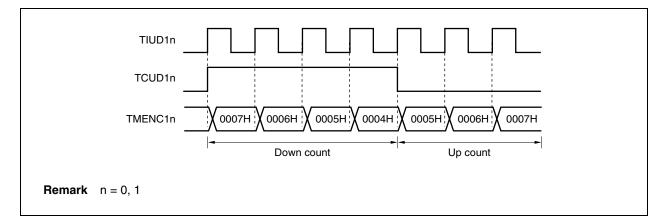

In mode 1, the following count operations are performed based on the level of the TCUD1n pin upon detection of the valid edge of the TIUD1n pin.

- TMENC1n down count operation when TCUD1n pin = high level
- TMENC1n up count operation when TCUD1n pin = low level

#### Figure 9-20. Mode 1 (When Rising Edge Is Specified as Valid Edge of TIUD1n Pin)

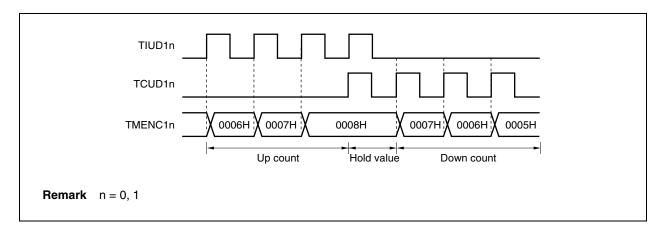

#### (ii) Mode 2 (PRM1n2 bit = 1, PRM1n1 bit = 0, PRM1n0 bit = 1)

The count conditions in mode 2 are as follows.

- TMENC1n up count upon detection of valid edge of TIUD1n pin
- TMENC1n down count upon detection of valid edge of TCUD1n pin

Caution If the count clock is simultaneously input to the TIUD1n pin and the TCUD1n pin, count operation is not performed and the immediately preceding value is held.

Figure 9-22. Mode 2 (When Rising Edge Is Specified as Valid Edge of TIUD1n, TCUD1n Pins)

#### (iii) Mode 3 (PRM1n2 = 1, PRM1n1 = 1, PRM1n0 = 0)

In mode 3, when two signals 90 degrees out of phase are input to the TIUD1n and TCUD1n pins, the level of the TCUD1n pin is sampled at the input of the valid edge of the TIUD1n pin (see **Figure 9-23**).

If the TCUD1n pin level sampled at the valid edge input to the TIUD1n pin is low, TMENC1n counts down when the valid edge is input to the TIUD1n pin.

If the TCUD1n pin level sampled at the valid edge input to the TIUD1n pin is high, TMENC1n counts up when the valid edge is input to the TIUD1n pin.

Figure 9-23. Mode 3 (When Rising Edge Is Specified as Valid Edge of TIUD1n pin)

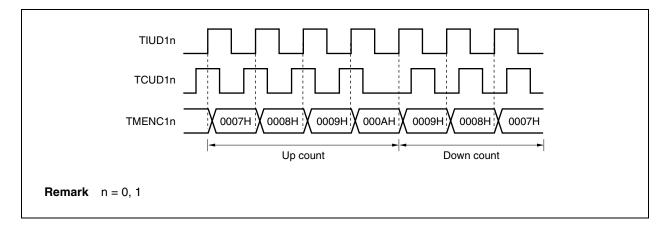

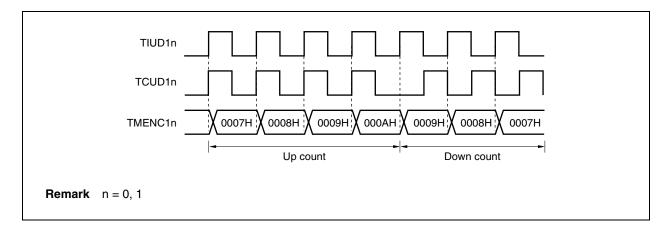

Figure 9-24. Mode 3 (When Rising Edge Is Specified as Valid Edge of TIUD1n Pin): In Case of Simultaneous TIUD1n, TCUD1n Pin Edge Timing

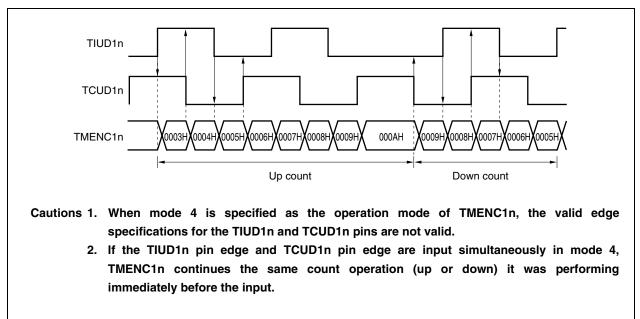

#### (iv) Mode 4 (PRM1n2 = 1, PRM1n1 = 1, PRM1n0 = 1)

In mode 4, when two signals out of phase are input to the TIUD1n and TCUD1n pins, up/down operation is automatically judged and counting is performed according to the timing shown in **Figure 9-25**.

In mode 4, counting is executed at both the rising and falling edges of the two signals input to the TIUD1n and TCUD1n pins. Therefore, TMENC1n counts four times per cycle of an input signal (×4 count).

**Remark** n = 0, 1

### (c) Operation in UDC mode A

### (i) Interval operation

The operations at the count clock following a match of the TMENC1n count value and the CM1n0 set value are as follows.

- In case of up count operation: TMENC1n is cleared to 0000H and the INTCM1n0 interrupt is generated.
- In case of down count operation: The TMENC1n count value is decremented (-1) and the INTCM1n0 interrupt is generated.

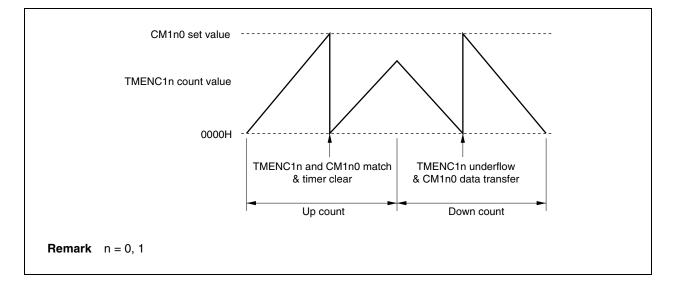

**Remark** The interval operation can be combined with the transfer operation.

### (ii) Transfer operation

The operations at the next count clock after the count value of TMENC1n becomes 0000H during a TMENC1n count down operation are as follows.

- In case of down count operation: The data held in CM1n0 is transferred.
- In case of up count operation: The TMENC1n count value is incremented (+1).
- Remarks 1. Transfer enable/disable can be set using the RLEN1n bit of the TMC1n register.2. The transfer operation can be combined with the interval operation.

## Figure 9-26. Example of TMENC1n Operation When Interval Operation and Transfer Operation Are Combined

# (iii) Compare function

TMENC1n connects two compare register (CM1n0, CM1n1) channels and two capture/compare register (CC1n0, CC1n1) channels.

When the TMENC1n count value and the set value of one of the compare registers match, a match interrupt (INTCM1n0, INTCM1n1, INTCC1n0<sup>Note</sup>, INTCC1n1<sup>Note</sup>) is output.

**Note** This match interrupt is generated when CC1n0 and CC1n1 are set to the compare register mode.

# (iv) Capture function

TMENC1n connects two capture/compare register (CC1n0, CC1n1) channels.

When CC1n0 and CC1n1 are set to the capture register mode, the value of TMENC1n is captured in synchronization with the corresponding capture trigger signal.

When CC1n0 and CC1n1 are set to the capture register mode, a capture interrupt (INTCC1n0, INTCC1n1) is generated upon detection of the valid edge.

### (d) Operation in UDC mode B

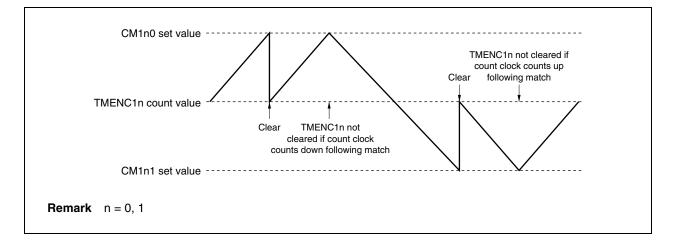

### (i) Basic operation

The operations at the next count clock after the count value of TMENC1n and the CM1n0 set value match when TMENC1n is in UDC mode B are as follows.

- In case of up count operation: TMENC1n is cleared to 0000H and the INTCM1n0 interrupt is generated.
- In case of down count operation: The TMENC1n count value is decremented (-1).

The operations at the next count clock after the count value of TMENC1n and the CM1n1 set value match when TMENC1n is in UDC mode B are as follows.

- In case of up count operation: The TMENC1n count value is incremented (+1).
- In case of down count operation: TMENC1n is cleared to 0000H and the INTCM1n1 interrupt is generated.

### (ii) Compare function

TMENC1n connects two compare register (CM1n0, CM1n1) channels and two capture/compare register (CC1n0, CC1n1) channels.

When the TMENC1n count value and the set value of one of the compare registers match, a match interrupt (INTCM1n0 (only during up count operation), INTCM1n1 (only during down count operation), INTCC1n0<sup>Note</sup>, INTCC1n1<sup>Note</sup>) is output.

Note This match interrupt is generated when CC1n0 and CC1n1 are set to the compare register mode.

# (iii) Capture function

TMENC1n connects two capture/compare register (CC1n0, CC1n1) channels.

When CC1n0 and CC1n1 are set to the capture register mode, the value of TMENC1n is captured in synchronization with the corresponding capture trigger signal.

When CC1n0 and CC1n1 are set to the capture register mode, a capture interrupt (INTCC1n0, INTCC1n1) is generated upon detection of the valid edge.

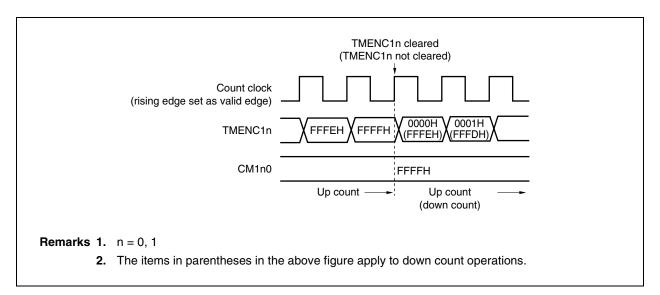

### 9.3.7 Supplementary description of internal operation

# (1) Clearing of count value in UDC mode B

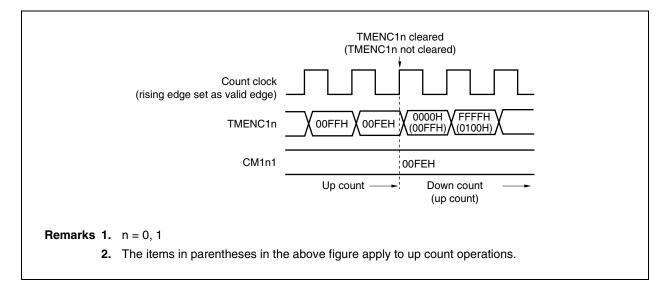

When TMENC1n is in UDC mode B, the count value clear operation is as follows.

- In case of TMENC1n up count operation: TMENC1n is cleared upon match with CM1n0
- In case of TMENC1n down count operation: TMENC1n is cleared upon match with CM1n1

### Figure 9-28. Clear Operation upon Match with CM1n0 During TMENC1n Up Count Operation

### Figure 9-29. Clear Operation upon Match with CM1n1 During TMENC1n Down Count Operation

# (2) Clearing of count value upon occurrence of compare match

The internal operation during a TMENC1n clear operation upon occurrence of a compare match is as follows.

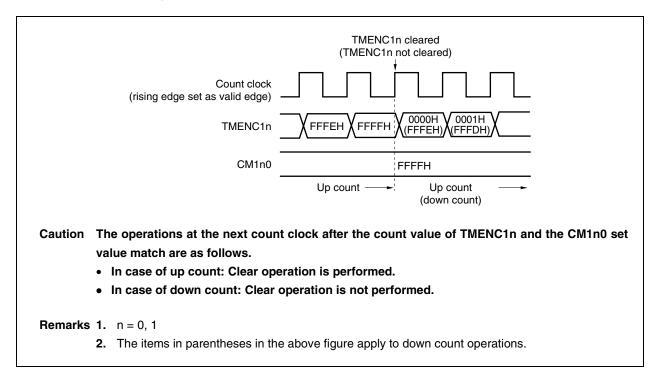

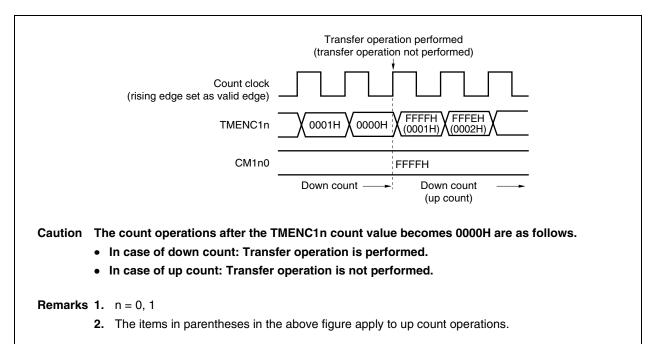

Figure 9-30. Count Value Clear Operation upon Compare Match

### (3) Transfer operation

The internal operation during TMENC1n transfer operation is as follows.

# (4) Interrupt signal output upon compare match

An interrupt signal is output when the count value of TMENC1n matches the set value of the CM1n0, CM1n1, CC1n0<sup>Note</sup>, or CC1n1<sup>Note</sup> register. The interrupt generation timing is as follows.

Note When CC1n0 and CC1n1 are set to the compare register mode.

<b>Remark</b> n = 0, 1	

An interrupt signal such as the one illustrated in Figure 9-32 is output at the next count following a match of the TMENC1n count value and the set value of the corresponding compare register.

# (5) UBD1n flag (bit 0 of STATUS1n register) operation

In the UDC mode (T1CMDn bit of TUM1n register = 1), the UBD1n flag changes as follows during TMENC1n up/down count operation at every internal operation clock.

### Figure 9-33. UBD1n Flag Operation

### (6) Overflow interrupt signal (INTOV1n) and underflow interrupt signal (INTUD1n)

- (a) The overflow interrupt signal (INTOV1n) is generated when the count value of TMENC1n has reached FFFFH and the next count operation is an up-count.
- (b) The underflow interrupt signal (INTUD1n) is generated when the count value of TMENC1n has reached 0000H and the next count operation is a down-count.
- (c) TMENC1n continues counting even after occurrence of an overflow or underflow, if a count edge is detected. If the condition of the underflow (0000H → FFFFH) is satisfied when the RLEN1n bit of the TMC1n register is 1 (enabling transfer), however, the set value of CM1n0 is transferred.
- (d) If the condition of the underflow (0000H → FFFFH) is satisfied with CM1n0 = FFFFH when the RLEN1n bit of the TMC1n register is cleared to 0 (disabling transfer), the INTCM1n0 interrupt and INTUD1n interrupt occur simultaneously.

# CHAPTER 10 SERIAL INTERFACE FUNCTION

# 10.1 Features

The serial interface function provides three types of serial interfaces equipped with five transmit/receive channels of which four channels can be used simultaneously.

The following three interface formats are available.

- (1) Asynchronous serial interfaces B0 and B1 (UARTB0 and UARTB1): 2 channels
- (2) Clocked serial interfaces 30 and 31 (CSI30 and CSI31): 2 channels
- (3) USB function controller (USBF): 1 channel

Remark For details of the USB function, see CHAPTER 11 USB FUNCTION CONTROLLER (USBF).

UARTB0 and UARTB1, which use the method of transmitting/receiving one byte of serial data following a start bit, enable full-duplex communication to be performed.

CSI30 and CSI31 transfer data according to three types of signals (3-wire serial I/O). These signals are the serial clock ( $\overline{SCK0}$  and  $\overline{SCK1}$ ), serial input (SI0 and SI1), and serial output (SO0 and SO1) signals.

The USB supports full-speed transfer of 12 Mbps and consists of seven endpoints.

### 10.1.1 Switching between UARTB0 and CSI30 modes

In the V850E/ME2, since UARTB0 and CSI30 are alternate function pins, they cannot be used at the same time. The registers must be set in advance.

### 10.2.2 Configuration

UARTBn is controlled by UARTBn control register 0 (UBnCTL0), the UARTBn status register (UBnSTR), UARTBn control register 2 (UBnCTL2), UARTBn FIFO control register 0 (UBnFIC0), UARTBn FIFO control register 1 (UBnFIC1), UARTBn FIFO control register 2 (UBnFIC2), UARTBn FIFO status register 0 (UBnFIS0), and UARTBn FIFO status register 1 (UBnFIS1) (n = 0, 1). Receive data is stored in a receive data register (the UBnRX register in the single mode or receive FIFOn in the FIFO mode (the UBnRXAP register)) and transmit data is written to a transmit data register (the UBnTX register in the single mode or transmit FIFO mode). If a reception error (such as a parity error or a framing error) occurs in the FIFO mode, the error data can be identified by reading UARTBn receive data register AP (UBnRXAP) in 16-bit (halfword) units.

Figure 10-1 shows the configuration of the asynchronous serial interface.

# (1) UARTBn control register 0 (UBnCTL0) (n = 0, 1)

This register controls the transfer operation of UARTBn.

# (2) UARTBn status register (UBnSTR) (n = 0, 1)

This register indicates the transfer status during transmission and the contents of a reception error. The status flag of this register, which indicates the transfer status during transmission, indicates the data retention status of transmit shift register n and transmit data register n (the UBnTX register in the single mode or transmit FIFOn in the FIFO mode). Each reception error flag is set to 1 when a reception error occurs, and cleared to 0 when 0 is written to the UBnSTR register.

# (3) UARTBn control register 2 (UBnCTL2) (n = 0, 1)

This register is used to specify the division rate by which to control the baud rate (serial transfer speed) of UARTBn.

### (4) UARTBn FIFO control register 0 (UBnFIC0) (n = 0, 1)

This register is used to select the operation mode of UARTBn, clear the transmit FIFOn/receive FIFOn that becomes valid in the FIFO mode, and specify the timing mode in which the transmission completion interrupt (UBTITn)/reception completion interrupt (UBTIRn) occurs.

### (5) UARTBn FIFO control register 1 (UBnFIC1) (n = 0, 1)

This register is valid in the FIFO mode. It generates a reception timeout interrupt request (UBTITOn) if data is stored in the receive FIFOn when the next data does not come (start bit is not detected) even after the reception wait time of the next data has elapsed.

### (6) UARTBn FIFO control register 2 (UBnFIC2) (n = 0, 1)

This register is valid in the FIFO mode. It is used to set the timing to generate the transmission completion interrupt (UBTITn)/reception completion interrupt (UBTIRn), using the number of data transmitted or received as a trigger.

### (7) UARTBn FIFO status register 0 (UBnFIS0) (n = 0, 1)

This register is valid in the FIFO mode. The number of bytes of data stored in the receive FIFO can be read from this register.

# (8) UARTBn FIFO status register 1 (UBnFIS1) (n = 0, 1)

This register is valid in the FIFO mode. The number of vacant bytes of the transmit FIFOn can be read from this register.

### (9) Receive shift register n (n = 0, 1)

\*

This is a shift register that converts the serial data that was input to the RXDn pin into parallel data. One byte of data is received, and if a stop bit is detected, the received data is transferred to receive data register n. This register cannot be directly manipulated.

### (10) UARTBn receive data register AP (UBnRXAP), UARTBn receive data register (UBnRX) (n = 0, 1)

Receive data register n holds receive data. In the single mode, the 8-bit  $\times$  1-stage UBnRX register is used. The 16-bit  $\times$  16-stage receive FIFOn (UBnRXAP register) is used in the FIFO mode.

The receive data is stored in the lower 8 bits of the receive FIFOn (UBnRXAP register) and the error information of the received data is stored in the higher 8 bits (bit 8 and bit 9). If a reception error (such as a parity error or a framing error) occurs in the FIFO mode, the error data can be identified by reading the UBnRXAP register in 16-bit (halfword) units (error information is appended as UBnPEF bit = 1 or UBnFEF bit = 1). When the lower 8 bits of the UBnRXAP register are read in 8-bit (byte) units, the higher 8 bits are discarded. Therefore, if no error has occurred, the receive data of the UBnRXAP register can be read consecutively by being read in 8-bit (byte) units in the same way as the UBnRX register.

When 7-bit length data is received with the LSB first, the received data is transferred to bits 6 to 0 of receive data register n from the LSB (bit 0), with the MSB (bit 7) always being 0. When data is received with the MSB first, the received data is transferred to bits 7 to 1 of receive data register n from the MSB (bit 7), with the LSB (bit 0) always being 0. If an overrun error occurs, the receive data at that time is not transferred to receive data register n.

While reception is enabled, the received data is transferred from receive shift register n to receive data register n, in synchronization with the shift-in processing of one frame.

A reception completion interrupt request (UBTIRn) is generated by transferring the data to the UBnRX register in the single mode, or transferring the number of receive data set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register to receive FIFOn in the FIFO mode. If data is stored in receive FIFOn when the next data does not come (start bit is not detected) after the next data reception wait time specified by the UBnTC4 to UBnTC0 bits of the UBnFIC1 register has elapsed in the FIFO mode, a reception timeout interrupt request (UBTITOn) is generated.

### (11)Transmit shift register n (n = 0, 1)

This is a shift register that converts the parallel data that was transferred from transmit data register n into serial data.

When one byte of data is transferred from transmit data register n, transmit shift register n data is output from the TXDn pin.

This register cannot be directly manipulated.

# (12)UARTBn transmit data register n (UBnTX) (n = 0, 1)

Transmit data register n is a buffer for transmit data. The 8-bit  $\times$  1-stage UBnTX register is used as this buffer in the single mode. In the FIFO mode, the 8-bit  $\times$  16-stage transmit FIFOn is used.

When 7-bit length data is transmitted with the LSB first, bits 6 to 0 of transmit data register n are transmitted as the transmit data from the LSB (bit 0) with the MSB (bit 7) always being 0. When data is transmitted with the MSB first, bits 7 to 1 of transmit data register n are transmitted as the transmit data from the MSB (bit 7) with the LSB (bit 0) always being 0.

In the single mode, transmission is started by writing transmit data to the UBnTX register while transmission is enabled (UBnTXE bit = 1 in the UBnCTL0 register). When writing the transmit data to the UBnTX register is enabled (when 1-byte data is transferred from the UBnTX register to transmit shift register n), a transmission completion interrupt request (UBTITn) is generated.

In the FIFO mode, transmission is started by writing at least the number of transmit data set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register and 16 bytes or less to transmit FIFOn and then enabling transmission (UBnTXE bit = 1). When the number of transmit data set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register have been transferred from transmit FIFOn to transmit shift register n (transmit data of the number set as the trigger can be written), a transmission completion interrupt request (UBTITn) is generated. In the FIFO mode, a FIFO transmits of completion interrupt request (UBTIFn) is generated when there is no more data in transmit FIFOn and transmit shift register n (when FIFOn and the register become empty).

### (13) Timeout counter

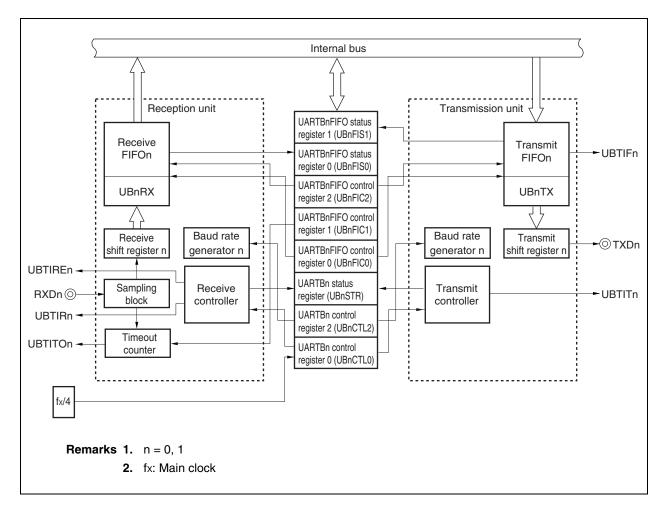

\*

This counter is used to recognize that data exists (remains) in receive FIFOn when the number of received data does not reach the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register, and is valid only in the FIFO mode.

If data is stored in receive FIFOn when the next data does not come (start bit is not detected) after the next data reception wait time specified by the UBnTC4 to UBnTC0 bits of the UBnFIC1 register has elapsed after the stop bit has been received, a reception timeout interrupt request (UBTITOn) is generated.

# (14) Sampling block

This block samples the RXDn signal at the rising edge of the input clock (fx/4) (fx: main clock). If the same sampling value is detected two times, output of the match detector changes, and the value is sampled as input data. Data of less than one clock width is judged as noise and is not transmitted to the internal circuitry.

# 10.2.3 Control registers

# (1) UARTBn control register 0 (UBnCTL0) (n = 0, 1)

The UBnCTL0 register controls the transfer operations of UARTBn. This register can be read or written in 8-bit or 1-bit units.

- Cautions 1. When using UARTBn, set the external pins related to the UARTBn function in the control mode, set UARTBn control register 2 (UBnCTL2). Then set the UBnPWR bit to 1 before setting the other bits.
  - 2. Be sure to input a high level to the RXDn pin when setting the external pins related to the UARTBn function in the control mode. If a low level is input, it is judged that a falling edge is input after the UBnRXE bit has been set to 1, and reception may be started.

0	UBnSL	Specifies the stop bit length of the transmit data. 0: 1 bit 1: 2 bits Cautions 1. To overwrite the UBnSL bit, first clear the UBnTXE bit to 0. 2. Since reception always operates by using a single stop bit length, the UBnSL bit setting does not affect receive operations.

**Remarks 1.** When reception is disabled, receive shift register n does not detect a start bit. No shift-in processing or transfer processing to receive data register n is performed, and the contents of receive data register n are retained.

When reception is enabled, the receive shift operation starts, in synchronization with the detection of the start bit, and when the reception of one frame is completed, the contents of receive shift register n are transferred to receive data register n. A reception completion interrupt (UBTIRn) is also generated, in synchronization with the transfer to receive data register n (in FIFO mode, transfer triggered by reaching set number of receive data).

If data is stored in receive FIFOn when the next data does not come (start bit is not detected) after the next data reception wait time specified by the UBnTC4 to UBnTC0 bits of the UBnFIC1 register has elapsed in the FIFO mode, a reception timeout interrupt request (UBTITOn) is generated.

**2.** n = 0, 1

# (2) UARTBn status register (UBnSTR) (n = 0, 1)

The UBnSTR register indicates the transfer status and reception error contents while UARTBn is transmitting data.

The status flag that indicates the transfer status during transmission indicates the data retention status of transmit shift register n and transmit data register n (the UBnTX register in the single mode or transmit FIFOn in the FIFO mode). The status flag that indicates a reception error holds its status until it is cleared to 0. This register can be read or written in 8-bit or 1-bit units.

# Caution When the UBnPWR bit or UBnRXE bit of the UBnCTL0 register is cleared to 0, or when 0 is written to the UBnSTR register, the UBnOVF, UBnPE, UBnFE, and UBnOVE bits of the UBnSTR register are cleared to 0.

# (3) UARTBn control register 2 (UBnCTL2) (n = 0, 1)

The UBnCTL2 register is used to specify the division ratio by which to control the baud rate (serial transfer speed) of UARTBn.

This register can be read or written in 16-bit units.

# Caution When rewriting the UBnBRS15 to UBnBRS0 bits of this register, clear the UBnTXE and UBnRXE bits of the UBnCTL0 register to 0 or clear the UBnPWR bit (n = 0, 1).

# (4) UARTBn transmit data register (UBnTX) (n = 0, 1)

The UBnTX register is used to set transmit data. It functions as the 8-bit  $\times$  1-stage UBnTX register, in the single mode (UBnMOD bit = 0 in the UBnFIC0 register), and as the 8-bit  $\times$  16-stage transmit FIFOn in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register).

In the single mode, transmission is started by writing transmit data to the UBnTX register when transmission is enabled (the UBnTXE bit = 1 in the UBnCTL0 register). When data can be written to the UBnTX register (when 1 byte of data is transferred from the UBnTX register to transmit shift register n), a transmission completion interrupt request (UBTITn) is generated.

In the FIFO mode, transmission is started by enabling transmission (UBnTXE bit = 1) after writing at least the number of transmit data set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register and 16 bytes or less to transmit FIFOn. When the number of transmit data set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register have been transferred from transmit FIFOn to transmit shift register n (transmit data of the number set as the trigger can be written to transmit FIFOn), a transmission completion interrupt request (UBTITn) is generated. In the FIFO mode, a FIFO transmission completion interrupt request (UBTIFn) is generated when there is no more data in transmit FIFOn and transmit shift register n (when the FIFOn and register become empty).

For the generation timing of the interrupt, see **10.2.4** Interrupt requests.

When 7-bit length data is transmitted with the LSB first, bits 6 to 0 of transmit data register n are transmitted as the transmit data from the LSB (bit 0) with the MSB (bit 7) always being 0. When data is transmitted with the MSB first, bits 7 to 1 of transmit data register n are transmitted as the transmit data from the MSB (bit 7) with the LSB (bit 0) always being 0.

This register is write-only, in 8-bit units. Data is written to transmit data register n.

# (5) UARTBn receive data register AP (UBnRXAP), UARTBn receive data register (UBnRX) (n = 0, 1)

These registers store parallel data converted by receive shift register n. They function as the 8-bit  $\times$  1-stage UBnRX register, in the single mode (UBnMOD bit = 0 in the UBnFIC0 register), and as the 16-bit  $\times$  16-stage receive FIFOn (UBnRXAP register) in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register).

The receive data is stored in the lower 8 bits of the receive FIFOn (UBnRXAP register) and the error information of the received data is stored in the higher 8 bits (bit 8 and bit 9). If a reception error (such as a parity error or a framing error) occurs in the FIFO mode, the UBnRXAP register is read in 16-bit (halfword) units. In this way, the flag of the data stored in receive FIFOn can be checked (error information is appended as UBnPEF bit = 1 or UBnFEF bit = 1), so that the error data can be recognized (when the lower 8 bits of the UBnRXAP register are read in 8-bit (byte) units, the higher 8 bits are discarded. Therefore, if no error has occurred, the receive data of the UBnRXAP register can be read consecutively by being read in 8-bit (byte) units in the same way as the UBnRX register).

If reception is enabled (UBnRXE bit = 1 in the UBnCTL0 register), the receive data is transferred from receive shift register n to receive data register n, in synchronization with the completion of the shift-in processing of one frame.

By transferring the receive data to the UBnRX register in the single mode or by transferring the number of receive data set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register to the receive FIFOn in the FIFO mode, a reception completion interrupt request (UBTIRn) is generated. If data is stored in receive FIFOn when the next data does not come (start bit is not detected) even after the next data reception wait time specified by the UBnTC4 to UBnTC0 bits of the UBnFIC1 register has elapsed in the FIFO mode, a reception timeout interrupt request (UBTIRn) is generated.

For information about the timing for generating these interrupt requests, see 10.2.4 Interrupt requests.

If data is received with the LSB first when the data length is specified as 7 bits, the received data is transferred to bits 6 to 0 of receive data register n from the LSB (bit 0), with the MSB (bit 7) always being 0. If data is received with the MSB first, it is transferred to bits 7 to 1 of receive data register n from the MSB (bit 7) with the LSB (bit 0) always being 0. However, if an overrun error occurs, the receive data at that time is not transferred to receive data register n.

The UBnRXAP register is read-only, in 16-bit units. However, the lower 8 bits of the UBnRXAP register are read-only, in 8-bit units.

The UBnRX register is read-only, in 8-bit units.

In addition to reset input, the value of these registers can be set to FFH in the single mode or to 00FFH in the FIFO mode, by clearing the UBnPWR bit of the UBnCTL0 register to 0.

# Cautions 1. Because these registers serve as 8-bit registers in the single mode, the UBnPEF and UBnFEF bits cannot be read.

2. When no reception error has occurred in the FIFO mode, the receive data of the UBnRXAP register can be read consecutively by reading the lower 8 bits of the UBnRXAP register in 8-bit (byte) units. An 8-bit access to the higher 8 bits is prohibited. If they are accessed, the operation is not guaranteed.

# (6) UARTBn FIFO control register 0 (UBnFIC0) (n = 0, 1)

The UBnFIC0 register is used to select the operation mode of UARTBn and the functions that become valid in the FIFO mode (UBnMOD bit = 1). In the FIFO mode, it clears transmit FIFOn/receive FIFOn and specifies the timing mode in which the transmission completion interrupt (UBTITn)/reception completion interrupt (UBTIRn) is generated.

This register can be read or written in 8-bit or 1-bit units.

# (7) UARTBn FIFO control register 1 (UBnFIC1) (n = 0, 1)

The UBnFIC1 register is valid in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register). It generates a reception timeout interrupt request (UBTITOn) if data is stored in receive FIFOn when the next data does not come (start bit is not detected) after the lapse of the time set by the UBnTC4 to UBnTC0 bits (next data reception wait time), after the stop bit has been received.

This register can be read or written in 8-bit or 1-bit units.

# (8) UARTBn FIFO control register 2 (UBnFIC2) (n = 0, 1)

The UBnFIC2 register is valid in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register). It sets the timing of generating an interrupt, using the number of transmit/receive data as a trigger. When data is transmitted, the number of data transferred from transmit FIFOn is specified as the condition of generating the interrupt. When data is received, the number of data stored in receive FIFOn is specified as the interrupt generation condition.

This register can be read or written in 16-bit units.

When the higher 8 bits of the UBnFIC2 register can be used as the UBnFIC2H register and the lower 8 bits, as the UBnFIC2L register, these registers can be read or written in 8-bit units.

Caution Before writing data to the UBnFIC2 register, be sure to clear the UBnTXE bit (to disable transmission) and UBnRXE bit (to disable reception) of the UBnCTL0 register to 0. If data is written to the UBnFIC2 register with the UBnTXE or UBnRXE bit set to 1, the operation is not guaranteed.

# (10)UARTBn FIFO status register 1 (UBnFIS1) (n = 0, 1)

The UBnFIS1 register is valid in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register). This register can be used to read the number of vacant bytes of transmit FIFOn.

This register is read-only, in 8-bit units.

Caution The values of the UBnTB4 to UBnTB0 bits are reflected after transmit data has been written to the UBnTX register and then time of two cycles of fx/4 (fx: main clock) has passed. Therefore, care must be exercised when referencing the UBnFIS1 register after transmit data has been written to the UBnTX register.

### 10.2.4 Interrupt requests

The following five types of interrupt requests are generated from UARTBn (n = 0, 1).

- Reception error interrupt (UBTIREn)
- Reception completion interrupt (UBTIRn)
- Transmission completion interrupt (UBTITn)
- FIFO transmission completion interrupt (UBTIFn)
- Reception timeout interrupt (UBTITOn)

The default priorities among these five types of interrupt requests is, from high to low, reception error interrupt, reception completion interrupt, transmission completion interrupt, FIFO transmission completion interrupt, and reception timeout interrupt.

Interrupt	Priority
Reception error	1
Reception completion	2
Transmission completion	3
FIFO transmission completion	4
Reception timeout	5

### Table 10-2. Generated Interrupts and Default Priorities

### (1) Reception error interrupt (UBTIREn)

### (a) Single mode

When reception is enabled, a reception error interrupt is generated according to the logical OR of the three types of reception errors (parity error, framing error, overrun error) explained for the UBnSTR register.

When reception is disabled, no reception error interrupt is generated.

### (b) FIFO mode

When reception is enabled, a reception error interrupt is generated according to the logical OR of the three types of reception errors (parity error, framing error, overflow error) explained for the UBnSTR register.

When reception is disabled, no reception error interrupt is generated.

### (2) Reception completion interrupt (UBTIRn)

### (a) Single mode

When reception is enabled, a reception completion interrupt is generated if data is shifted into receive shift register n and stored in the UBnRX register (if the receive data can be read). When reception is disabled, no reception completion interrupt is generated.

### (b) FIFO mode

When reception is enabled, a reception completion interrupt is generated if data is shifted into receive shift register n and receive data of the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register is transferred to receive FIFOn (if receive data of the specified number can be read). When reception is disabled, no reception completion interrupt is generated.

### (3) Transmission completion interrupt (UBTITn)

### (a) Single mode

The transmission completion interrupt is generated if transmit data of one frame, including 7 or 8 bits of characters, is shifted out from transmit shift register n and the UBnTX register becomes vacant (if transmit data can be written).

# (b) FIFO mode

The transmission completion interrupt is generated if transmit data of the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register is transferred to transmit shift register n from transmit FIFOn (if transmit data of the specified number can be written).

### (4) FIFO transmission completion interrupt (UBTIFn)

### (a) Single mode

Cannot be used.

### (b) FIFO mode

The FIFO transmission completion interrupt is generated when no more data is in transmit FIFOn and transmit shift register n (when the FIFO and register become empty). After the FIFO transmission completion interrupt has occurred, clear the interrupt held pending (UBTITn) in the pending mode (UBnITM bit = 0 in the UBnFIC0 register) by clearing the FIFO (UBnTFC bit = 1 in the UBnFIC0 register).

# Caution If the FIFO transmission completion interrupt is generated (all transmit data are not transmitted) because writing the next transmit data to transmit FIFOn is delayed, do not clear the FIFO.

### (5) Reception timeout interrupt (UBTITOn)

# (a) Single mode

Cannot be used.

## (b) FIFO mode

\*

The reception timeout interrupt is generated if data is stored in receive FIFOn when the next data does not come (start bit is not detected) even after the next data reception wait time specified by the UBnTC4 to UBnTC0 bits of the UBnFIC1 register has elapsed, when the timeout counter function is used (UBnTCE bit = 1 in the UBnFIC1 register).

The reception timeout interrupt is not generated while reception is disabled.

If receive data of the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register is not received, the timing of reading the number of receive data less than the specified number can be set by the reception timeout interrupt.

Since the timeout counter starts counting at start bit detection, a receive timeout interrupt does not occur if data of 1 character has not been received.

### 10.2.5 Control method

### (1) Single mode/FIFO mode

The single mode or FIFO mode can be selected by using the UBnMOD bit of the UBnFIC0 register.

### (a) Single mode

- Each of the UBnRX and UBnTX registers consists of 8 bits  $\times$  1 stage.
- When 1 byte of data is received, the UBTIRn interrupt is generated.
- If the next reception operation of UARTBn is completed before the receive data of the UBnRX register is read after the UBTIRn interrupt has been generated, the UBTIREn interrupt is generated and an overrun error occurs.

### (b) FIFO mode

- Receive FIFOn (UBnRXAP register) consists of 16 bits × 16 stages and transmit FIFOn consists of 8 bits × 16 stages.
- Receive FIFOn can recognize error data by reading the 16-bit UBnRXAP register only when a reception error (parity error or framing error) occurs.
- Transmission is started when transmission is enabled (UBnTXE bit = 1 in the UBnCTL0 register) after transmit data of at least the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register and 16 bytes or less are written to transmit FIFOn.
- The pending mode or pointer mode can be selected for the generation timing of the UBTITn and UBTIRn interrupts.

### (2) Pending mode/pointer mode

The pending mode or pointer mode can be selected by using the UBnITM and UBnIRM bits of the UBnFIC0 register in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register).

If transmission is started by writing data of more than double the amount set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register to transmit FIFOn, the transmission completion interrupt (UBTITn) may occur more than once. The reception completion interrupt (UBTIRn) may also occur more than once if the number of receive data set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register is 8 bytes or less in receive FIFOn. In the pending or pointer mode, it can be specified how an interrupt is handled after it has been held pending.

### (a) Pending mode

\*

\*

#### (i) During transmission (writing to transmit FIFOn)

If the data of the first transmission completion interrupt (UBTITn) is not written to transmit FIFOn after the interrupt has occurred, the second UBTITn interrupt does not occur (is held pending) even if the generation condition of the second UBTITn interrupt is satisfied (when transmit data of the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register is transferred from transmit FIFOn to the transmit shift register).

When data for the first UBTITn interrupt is later written to transmit FIFOn, the pending UBTITn interrupt is generated<sup>Note</sup>.

**Note** The number of pending interrupts is as follows.

When trigger is set to 1 byte (UBnTT3 to UBnTT0 bits of UBnFIC2 register = 0000): 15 times max. When trigger is set to 2 bytes (UBnTT3 to UBnTT0 bits of UBnFIC2 register = 0001): 7 times max.

When trigger is set to 6 bytes (UBnTT3 to UBnTT0 bits of UBnFIC2 register = 0101): 1 time max. When trigger is set to 7 bytes (UBnTT3 to UBnTT0 bits of UBnFIC2 register = 0110): 1 time max. When trigger is set to 8 bytes (UBnTT3 to UBnTT0 bits of UBnFIC2 register = 0111): 1 time max.

- In the pending mode, transmit data of the number set as the trigger by the UBnTT3 to UBnTT0 bits
  of the UBnFIC2 register is always written to transmit FIFOn when the transmission completion
  interrupt (UBTITn) occurs. Writing data to transmit FIFOn is prohibited if the data is more or less
  than the specified number. If data more or less than the specified number is written, the operation
  is not guaranteed.
- To write transmit data to transmit FIFOn by DMA, fix the UBnTT3 to UBnTT0 bits of the UBnFIC2 register to 0000 (set number of transmit data: 1 byte). If any other setting is made, the operation is not guaranteed.

### (ii) During reception (reading from receive FIFOn)

If data for the first reception completion interrupt (UBTIRn) is not read from receive FIFOn, the second UBTIRn interrupt does not occur (is held pending) even if the generation condition of the second UBTIRn is satisfied (if receive data of the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register can be read from receive FIFOn). When data for the first UBTIRn interrupt is later read from the receive FIFOn, the pending UBTIRn interrupt is generated<sup>Note</sup>.

**Note** The number of pending interrupts is as follows.

When trigger is set to 1 byte (UBnRT3 to UBnRT0 bits of UBnFIC2 register = 0000): 15 times max. When trigger is set to 2 bytes (UBnRT3 to UBnRT0 bits of UBnFIC2 register = 0001): 7 times max.

When trigger is set to 6 bytes (UbnRT3 to UBnRT0 bits of UBnFIC2 register = 0101): 1 time max. When trigger is set to 7 bytes (UBnRT3 to UBnRT0 bits of UBnFIC2 register = 0110): 1 time max. When trigger is set to 8 bytes (UBnRT3 to UBnRT0 bits of UBnFIC2 register = 0111): 1 time max.

- In the pending mode, receive data of the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register is always read from receive FIFOn when the reception completion interrupt (UBTIRn) occurs. Reading data from receive FIFOn is prohibited if the data is more or less than the specified number. If data more or less than the specified number is read, the operation is not guaranteed.
- To read receive data from receive FIFOn by DMA, fix the UBnRT3 to UBnRT0 bits of the UBnFIC2 register to 0000 (set number of receive data: 1 byte). If any other setting is made, the operation is not guaranteed.

### (b) Pointer mode

\*

### (i) During transmission (writing to transmit FIFOn)

- Each time the data of 1 byte is transferred to transmit shift register n from transmit FIFOn, a transmission completion interrupt (UBTITn) occurs.
- In the pointer mode, be sure to fix the UBnTT3 to UBnTT0 bits of the UBnFIC2 register to 0000 (set number of transmit data: 1 byte) as the number of transmit data set as the trigger for transmit FIFOn when the transmission completion interrupt (UBTITn) occurs. If any other setting is made, the operation is not guaranteed.
- Writing transmit data to transmit FIFOn by DMA is prohibited. The operation is not guaranteed if DMA control is used.
- After the transmission completion interrupt (UBTITn) has been acknowledged, data of the number of vacant bytes of transmit FIFOn can be written to transmit FIFOn by referencing the UBnFIS1 register.

#### (ii) During reception (reading from receive FIFOn)

- Each time the data of 1 byte is transferred to receive FIFOn from receive shift register n, a reception completion interrupt (UBTIRn) occurs.
- In the pointer mode, be sure to fix the UBnRT3 to UBnRT0 bits of the UBnFIC2 register to 0000 (set number of receive data: 1 byte) as the number of receive data set as the trigger for receive FIFOn when the reception completion interrupt (UBTIRn) occurs. If any other setting is made, the operation is not guaranteed.
- Reading receive data from receive FIFOn by DMA is prohibited. The operation is not guaranteed if DMA control is used.
- After the reception completion interrupt (UBTIRn) has been acknowledged, data of the number of bytes stored in receive FIFOn can be read from receive FIFOn by referencing the UBnFIS0 register. In some cases, however, data is not stored in receive FIFOn even though the UBTIRn interrupt is generated (UBnRB4 to UBnRB0 bits = 00000 in the UBnFIS0 register). In these cases, do not read data from receive FIFOn. Always read data from receive FIFOn when the number of bytes stored in receive FIFOn is 1 byte or more (UBnRB4 to UBnRB0 bits = other than 00000).

#### 10.2.6 Operation

#### (1) Data format

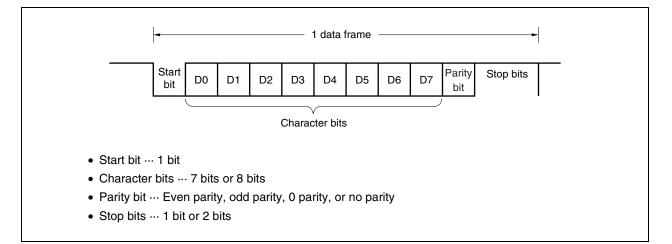

Full-duplex serial data transmission and reception can be performed.

The transmit/receive data format consists of one data frame containing a start bit, character bits, a parity bit, and stop bits as shown in Figure 10-2.

The character bit length within one data frame, the type of parity, and the stop bit length are specified by the UARTBn control register 0 (UBnCTL0) (n = 0, 1).

Also, data is transferred with LSB first/MSB first.

#### (2) Transmit operation

In the single mode (UBnMOD bit = 0 in the UBnFIC0 register), transmission is enabled when the UBnTXE bit of the UBnCTL0 register is set to 1, and transmission is started when transmit data is written to the UBnTX register (n = 0, 1).

In the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register), transmission is started when transmit data of at least the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register and 16 bytes or less is written to transmit FIFOn and then the UBnTXE bit is set to 1.

# Caution Setting the UBnTXE bit of the UBnCTL0 register to 1 before writing transmit data to transmit FIFOn in the FIFO mode is prohibited. The operation is not guaranteed if this setting is made.

#### (a) Transmission enabled state

This state is set by the UBnTXE bit in the UBnCTL0 register (n = 0, 1).

- UBnTXE = 1: Transmission enabled state
- UBnTXE = 0: Transmission disabled state

However, when the transmission enabled state is set, to use UARTB0, which shares pins with clocked serial interface 30 (CSI30), the CSICAE0 bit of clocked serial interface mode register 30 (CSIM30) should be cleared to 0.

Since UARTBn does not have a CTS (transmission enabled signal) input pin, a port should be used to confirm whether the destination is in the reception enabled state.

# (b) Starting a transmit operation

#### In single mode (UBnMOD bit = 0 in UBnFIC0 register)

In the single mode, transmission is started when transmit data is written to the UBnTX register while transmission is enabled (n = 0, 1).

#### In FIFO mode (UBnMOD bit = 1 in UBnFIC0 register)

In the FIFO mode, transmission is started when transmit data of at least the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register and 16 bytes or less is written to transmit FIFOn and then transmission is enabled (UBnTXE bit = 1).

Data in transmit data register n (UBnTX register in single mode or transmit FIFOn in the FIFO mode) is transferred to transmit shift register n when transmission is started. Then, transmit shift register n outputs data to the TXDn pin sequentially beginning with the LSB (the transmit data is transferred sequentially starting with the start bit). The start bit, parity bit, and stop bits are added automatically (n = 0, 1).

#### (c) Transmission interrupt request

#### (i) Transmission completion interrupt (UBTITn)

#### In single mode (UBnMOD bit = 0 in UBnFIC0 register)

In the single mode, the transmission completion interrupt (UBTITn) occurs when transmit data can be written to the UBnTX register (when 1 byte of data is transferred from the UBnTX register to transmit shift register n) (n = 0, 1).

#### • In FIFO mode (UBnMOD bit = 1 in UBnFIC0 register)

In the FIFO mode, the UBTITn interrupt occurs when transmit data of the number set as the trigger specified by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register is transferred from transmit FIFOn to transmit shift register n (if transmit data of the number set as the trigger can be written) (n = 0, 1).

#### • If pending mode is specified (UBnITM bit = 0 in UBnFIC0 register) in FIFO mode

If the pending mode is specified in the FIFO mode, the second UBTITn interrupt is held pending after the first UBTITn interrupt has occurred, until as many transmit data as the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register are written to transmit FIFOn, even if the generation condition of the second UBTITn interrupt is satisfied. When as many transmit data as the number set as the trigger are written to transmit FIFOn in response to the first UBTITn interrupt, the second pending UBTITn interrupt is generated (n = 0, 1).

#### If pointer mode is specified (UBnITM bit = 1 in UBnFIC0 register) in FIFO mode

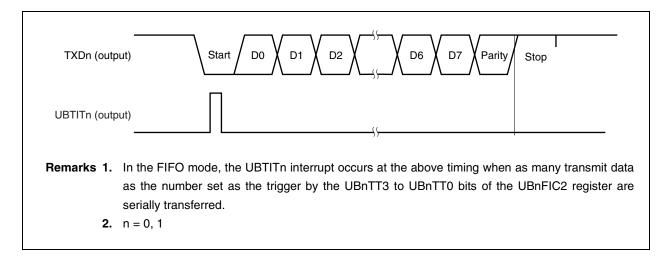

If the pointer mode is specified in the FIFO mode, the second UBTITn interrupt occurs when the generation condition of the second UBTITn interrupt is satisfied even if as many transmit data as the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register are not written to transmit FIFOn when the first UBTITn interrupt occurs (n = 0, 1).

#### (ii) FIFO transmission completion interrupt (UBTIFn)

The FIFO transmission completion interrupt (UBTIFn) occurs when no more data is in transmit FIFOn and transmit shift register n in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register) (n = 0, 1). After the UBTIFn interrupt has occurred, clear the pending UBTITn interrupt in the pending mode (UBnITM bit = 0 in the UBnFIC0 register) by clearing the FIFO (UBnTFC bit = 1 in the UBnFIC0 register). If the UBTIFn interrupt occurs because writing the next transmit data to transmit FIFOn is delayed (if all transmit data have not been transmitted), do not clear the FIFO.

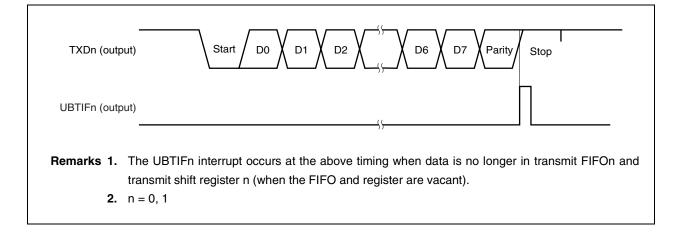

If the data to be transmitted next has not been written to transmit data register n, the transmit operation is suspended.

Caution In the single mode, the transmission completion interrupt (UBTITn) occurs when the UBnTX register becomes empty (when 1 byte of data is transferred from the UBnTX register to transmit shift register n). In the FIFO mode, the FIFO transmission completion interrupt (UBTIFn) occurs when data is no longer in transmit FIFOn and transmit shift register n (when the FIFO and register are vacant). However, the UBTITn interrupt or UBTIFn interrupt is not generated if transmit data register n becomes empty due to RESET input.

#### Figure 10-3. Timing of Asynchronous Serial Interface Transmission Completion Interrupt (UBTITn)

Figure 10-4. Timing of Asynchronous Serial Interface FIFO Transmission Completion Interrupt (UBTIFn)

#### (3) Continuous transmission operation

#### • In single mode (UBnMOD bit = 0 in UBnFIC0 register)

In the single mode, the next data can be written to the UBnTX register as soon as transmit shift register n has started a shift operation (n = 0, 1). The timing of transfer can be identified by the transmission completion interrupt (UBTITn). By writing the next transmit data to the UBnTX register via the UBTITn interrupt within one data frame transmission period, data can be transmitted without an interval and an efficient communication rate can be realized.

# Caution Before executing initialization during transmission processing, confirm that the UBnTSF bit of the UBnSTR register is 0. If initialization is executed while the UBnTSF bit is 1, the transmit data is not guaranteed.

#### • If pending mode is specified (UBnITM bit = 0 in UBnFIC0 register) in FIFO mode

If transmit data of at least the number set as the transmit trigger by UBnTT3 to UBnTT0 bits of the UBnFIC2 register and 16 bytes or less is written to transmit FIFOn, transmission starts.

If the pending mode is specified in the FIFO mode, as many of the next transmit data as the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register can be written to transmit FIFOn as soon as transmit shift register n has started shifting the last data of the specified number of data. The timing of transfer can be identified by the UBTITn interrupt. By writing as many of the next transmit data as the number set as the trigger to transmit FIFOn or writing the data to the FIFO within the transmission period of the data in transmit FIFOn via the UBTITn interrupt, data can be transmitted without an interval and an efficient communication rate can be realized.

Caution Before executing initialization during transmission processing, confirm that the UBnTSF bit of the UBnSTR register is 0 (this can also be done by the FIFO transmission completion interrupt (UBTIFn)). If initialization is executed while the UBnTSF bit is 1, the transmit data is not guaranteed. To write transmit data to transmit FIFOn by DMA, set the number of transmit data specified as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register to 1 byte. Otherwise, the operation will not be guaranteed.

#### • If pointer mode is specified (UBnITM bit = 1 in UBnFIC0 register) in FIFO mode

If the pointer mode is specified in the FIFO mode, a UBTITn interrupt occurs and the next data can be written to transmit FIFOn as soon as transmit shift register n has started shifting the number of transmit data set as the trigger. At this time, as many data as the number of vacant bytes of transmit FIFOn can be written by referencing the UBnFIS1 register. The timing of transfer can be identified by the UBTITn interrupt. By writing as many of the next transmit data as the number specified as the trigger to transmit FIFOn (= 1 byte) or writing the data to the FIFO within the transmission period of the data in transmit FIFOn via the UBTITn interrupt, data can be transmitted without an interval and an efficient communication rate can be realized.

Caution Before executing initialization during transmission processing, confirm that the UBnTSF bit of the UBnSTR register is 0 (this can also be done by the FIFO transmission completion interrupt (UBTIFn)). If initialization is executed while the UBnTSF bit is 1, the transmit data is not guaranteed.

#### (4) Receive operation

The awaiting reception state is set by setting the UBnPWR bit to 1 in the UBnCTL0 register and then setting UBnRXE to 1 in the UBnCTL0 register (n = 0, 1). RXDn pin sampling begins and a start bit is detected. When the start bit is detected, the receive operation begins, and data is stored sequentially in receive shift register n according to the baud rate that was set.

In the single mode (UBnMOD bit = 0 in the UBnFIC0 register), a reception completion interrupt (UBTIRn) is generated each time the reception of one frame of data is completed. Normally, the receive data is transferred from the UBnRX register to memory by this interrupt servicing.

In the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register), the UBTIRn interrupt occurs when as many receive data as the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register are transferred to receive FIFOn.

If the pending mode is specified (UBnIRM bit = 0 in the UBnFIC0 register) in the FIFO mode, as many receive data as the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register can be read from receive FIFOn.

If the pointer mode is specified (UBnIRM bit = 1 in the UBnFIC0 register) in the FIFO mode, as many data as the number of bytes stored in receive FIFOn (0 bytes or more) can be read from receive FIFOn by referencing the number of receive data specified as the trigger by the UBnRT3 to UBnRT0 bits (1 byte) or the UBnFIS0 register.

Caution If the pointer mode is specified in the FIFO mode and if as many data as the number of bytes stored in receive FIFOn are read by referencing the UBnFIS0 register, no data may be stored in receive FIFOn (UBnRB4 to UBnRB0 bits = 00000 in the UBnFIS0 register) even though the reception completion interrupt (UBTIRn) has occurred. In this case, do not read data from receive FIFOn. Be sure to read data from receive FIFOn after confirming that the number of bytes stored in receive FIFOn = 1 byte or more (UBnRB4 to UBnRB0 bits = other than 00000).

#### (a) Reception enabled state

This state is set by the UBnRXE bit in the UBnCTL0 register (n = 0, 1).

- UBnRXE = 1: Reception enabled state
- UBnRXE = 0: Reception disabled state

However, when the reception enabled state is set, to use UARTB0, which shares pins with clocked serial interface 30 (CSI30), the operation of CSI30 must be disabled by clearing the CSICAE0 bit of clocked serial interface mode register 30 (CSIM30) to 0 (n = 0, 1).

In the reception disabled state, the reception hardware stands by in the initial state. At this time, the reception completion interrupt or reception error interrupt does not occur, and the contents of receive data register n (UBnRX register in the single mode or receive FIFOn in the FIFO mode (UBnRXAP register)) are retained.

# (b) Starting a receive operation

A receive operation is started by the detection of a start bit. The RXDn pin is sampled using the serial clock from UARTBn control register 2 (UBnCTL2) (n = 0, 1).

#### (c) Reception completion interrupt

### (i) Reception completion interrupt (UBTIRn)

#### In single mode (UBnMOD bit = 0 in UBnFIC0 register)

When UBnRXE bit = 1 in the UBnCTL0 register and the reception of one frame of data is completed (the stop bit is detected) in the single mode, a reception completion interrupt request (UBTIRn) is generated and the receive data in receive shift register n is transferred to the UBnRX register at the same time (n = 0, 1).

Also, if an overrun error occurs, the receive data at that time is not transferred to the UBnRX register, and a reception error interrupt (UBTIREn) is generated.

If a parity error or framing error occurs during the reception operation, the reception operation continues up to the position at which the stop bit is received. After completion of reception, an UBTIREn interrupt occurs (the receive data in receive shift register n is transferred to the UBnRX register).

If the UBnRXE bit is reset (0) during a receive operation, the receive operation is immediately stopped. At this time, the contents of the UBnRX register remain unchanged, the contents of the UARTBn status register (UBnSTR) are cleared, and the UBTIRn and UBTIREn interrupts do not occur.

No UBTIRn interrupt is generated when UBnRXE = 0 (reception is disabled).

#### • In FIFO mode (UBnMOD bit = 1 in UBnFIC0 register)

In the FIFO mode, the reception completion interrupt (UBTIRn) occurs when data of one frame has been received (stop bit is detected) and when as many receive data as the number specified as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register are transferred from receive shift register n to receive FIFOn (n = 0, 1). If an overflow error occurs, the receive data is not transferred to receive FIFOn and the reception error interrupt (UBTIREn) occurs.

If a parity error or framing error occurs during reception, reception continues up to the reception position of the stop bit. After reception has been completed, the UBTIREn interrupt occurs and the receive data in receive shift register n is transferred to receive FIFOn. At this time, error information is appended as the UBnPEF or UBnFEF bit = 1 in the UBnRXAP register. If the UBTIREn interrupt occurs, the error data can be recognized by reading receive FIFOn as a 16-bit register, UBnRXAP.

# (ii) Reception timeout interrupt (UBTITOn) (in FIFO mode only)

When the timeout counter function (UBnTCE bit = 1 in the UBnFIC1 register) is used in the FIFO mode, the reception timeout interrupt (UBTITOn) occurs if the next data does not come even after the next data reception wait time specified by the UBnTC4 to UBnTC0 bits of the UBnFIC1 register has elapsed and if data is stored in receive FIFOn (n = 0, 1).

The UBTITOn interrupt does not occur while reception is disabled.

If as many receive data as the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register are not received, the timing of reading less receive data than the specified number can be set by the UBTITOn interrupt.

\*

Since the timeout counter starts counting at start bit detection, a receive timeout interrupt does not occur if data of 1 character has not been received.

#### (5) Reception error

In the single mode (UBnMOD bit = 0 in the UBnFIC0 register), the three types of errors that can occur during a receive operation are a parity error, framing error, and overrun error. In the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register), the three types of errors that can occur during a receive operation are a parity error, framing error, and overflow error.

As a result of data reception, the UBnPE, UBnFE, or UBnOVE bit of the UBnSTR register is set to 1 if a parity error, framing error, or overrun error occurs in the single mode. The UBnOVF bit of the UBnSTR register is set to 1 if an overflow error occurs in the FIFO mode. The UBnPEF or UBnFEF bit of the UBnRXAP register is set to 1 if a parity error or framing error occurs in the FIFO mode. At the same time, a reception error interrupt (UBTIREn) occurs. The contents of the error can be detected by reading the contents of the UBnSTR or UBnRXAP register.

The contents of the UBnSTR register are reset when 0 is written to the UBnOVF, UBnPE, UBnFE, or UBnOVE bit, or the UBnPWR or UBnRXE bit of the UBnCTL0 register. The contents of the UBnRXAP register are reset when 0 is written to the UBnPWR bit of the UBnCTL0 register.

Error Flag	Valid Operation Mode	Error Flag	Reception Error	Cause
UBnPE	Single mode	UBnPE	Parity error	The parity specification during transmission does not match the parity of the receive data
UBnFE		UBnFE	Framing error	No stop bit detected
UBnOVE		UBnOVE	Overrun error	The reception of the next data is completed before data is read from the UBnRX register
UBnOVF	FIFO mode	UBnOVF	Overflow error	The reception of the next data is completed while receive FIFOn is full and before data is read.
UBnPEF		UBnPEF	Parity error	The parity specification during transmission does not match the parity of the data to be received.
UBnFEF		UBnFEF	Framing error	The stop bit is not detected when the target data is loaded.

#### (6) Parity types and corresponding operation

A parity bit is used to detect a bit error in communication data. Normally, the same type of parity bit is used at the transmission and reception sides.

# (a) Even parity

#### (i) During transmission

The parity bit is controlled so that the number of bits with the value "1" within the transmit data including the parity bit is even. The parity bit value is as follows.

- If the number of bits with the value "1" within the transmit data is odd: 1
- If the number of bits with the value "1" within the transmit data is even: 0

#### (ii) During reception

The number of bits with the value "1" within the receive data including the parity bit is counted, and a parity error is generated if this number is odd.

# (b) Odd parity

#### (i) During transmission

In contrast to even parity, the parity bit is controlled so that the number of bits with the value "1" within the transmit data including the parity bit is odd. The parity bit value is as follows.

- If the number of bits with the value "1" within the transmit data is odd: 0
- If the number of bits with the value "1" within the transmit data is even: 1

#### (ii) During reception

The number of bits with the value "1" within the receive data including the parity bit is counted, and a parity error is generated if this number is even.

#### (c) 0 parity

During transmission the parity bit is set to "0" regardless of the transmit data.

During reception, no parity bit check is performed. Therefore, no parity error is generated regardless of whether the parity bit is "0" or "1".

#### (d) No parity

No parity bit is added to the transmit data.

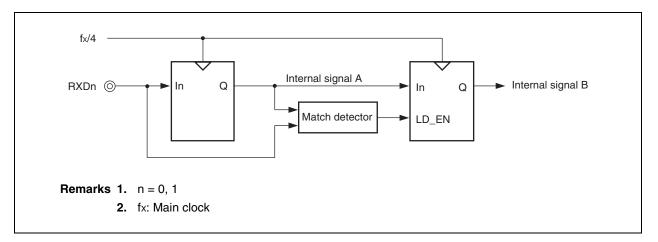

During reception, the receive operation is performed as if there were no parity bit. Since there is no parity bit, no parity error is generated.

### (7) Receive data noise filter

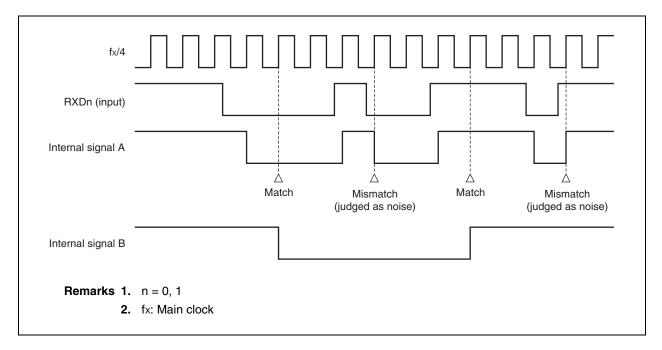

The RXDn signal is sampled at the rising edge of the input clock (fx/4) (fx: main clock). If the same sampling value is obtained twice, the match detector output changes, and this output is sampled as input data. Therefore, data not exceeding one clock width is judged to be noise and is not delivered to the internal circuit (see **Figure 10-7**).

Also, since the circuit is configured as shown in Figure 10-6, internal processing during a receive operation is delayed by up to 2 clocks according to the external signal status.

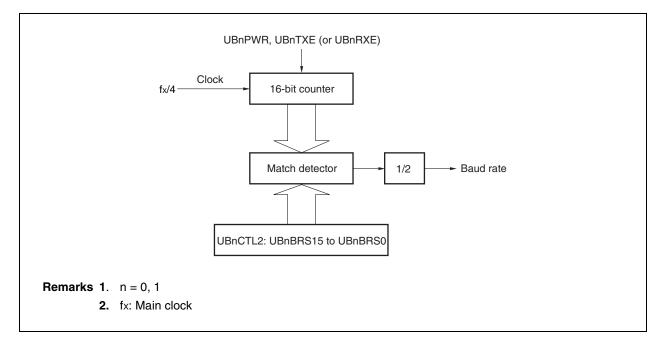

# 10.2.7 Dedicated baud rate generators 0, 1 (BRG0, BRG1)

A dedicated baud rate generator, which consists of a 16-bit programmable counter, generates serial clocks during transmission/reception in UARTBn. The dedicated baud rate generator output can be selected as the serial clock for each channel.

Separate 16-bit counters exist for transmission and for reception. The baud rate for transmission/reception is the same at the same channel.

#### (1) Baud rate generator configuration

#### Figure 10-8. Baud Rate Generator Configuration

# (a) Base clock (Clock)

When UBnPWR bit = 1 in the UBnCTL0 register, the input clock (fx/4) is supplied to the transmission/reception unit (fx: main clock). This clock is called the base clock. When UBnPWR = 0, the clock signal is fixed at low level.

# (2) Serial clock generation

A serial clock can be generated according to the settings of the UBnCTL2 register (n = 0, 1). The 16-bit counter divisor value can be selected according to the UBnBRS15 to UBnBRS0 bits of the UBnCTL2 register.

# (a) Baud rate

The baud rate is the value obtained according to the following formula.

Baud rate = 
$$\frac{\text{Base clock frequency}}{2 \times k}$$
 [bps]

Base clock frequency = fx/4 (fx: main clock)

k = Value set according to UBnBRS15 to UBnBRS0 bits of UBnCTL2 register (k = 4, 5, 6, ..., 65,535)

# (b) Baud rate error

The baud rate error is obtained according to the following formula.

Example: Main clock (fx) = 150 MHz = 150,000,000 Hz Settings of UBnBRS15 to UBnBRS0 bits in UBnCTL2 register = 000000001111010B (k = 122) Target baud rate = 153,600 bps Baud rate = 150 M/4/(2 × 122) = 150,000,000/4/(2 × 122) = 153,689 [bps] Error = (153,689/153,600 - 1) × 100 = 0.058 [%]

#### (4) Allowable baud rate range during reception

The degree to which a discrepancy from the transmission destination's baud rate is allowed during reception is shown below.

# Caution The equations described below should be used to set the baud rate error during reception so that it always is within the allowable error range.

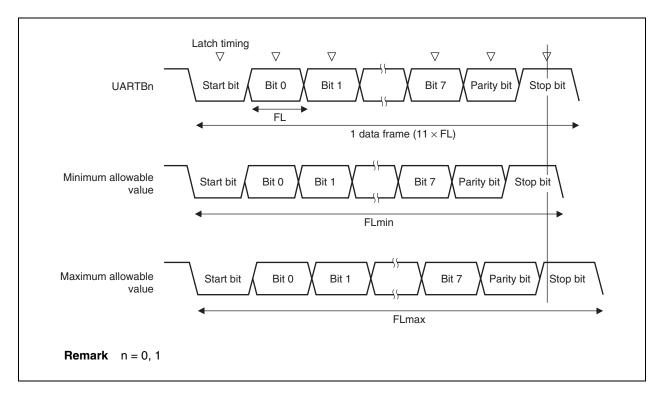

Figure 10-9. Allowable Baud Rate Range During Reception

As shown in Figure 10-9, after the start bit is detected, the receive data latch timing is determined according to the counter that was set by the UBnCTL2 register. If all data up to the final data (stop bit) is in time for this latch timing, the data can be received normally.

Applying this to 11-bit reception is, theoretically, as follows.

 $FL = (Brate)^{-1}$ 

Brate: UARTBn baud rate (n = 0, 1)

k: UBnCTL2 setting value (n = 0, 1)

FL: 1-bit data length

Latch timing margin: 2 clocks

Minimum allowable value: FLmin = 
$$11 \times FL - \frac{k-2}{2k} \times FL = \frac{21k+2}{2k} FL$$

Therefore, the maximum baud rate that can be received at the transfer destination is as follows.

$$\mathsf{BRmax} = (\mathsf{FLmin}/11)^{-1} = \frac{22k}{21k+2}$$
 Brate

Similarly, the maximum allowable value can be obtained as follows.

$$\frac{10}{11} \times FLmax = 11 \times FL - \frac{k+2}{2 \times k} \times FL = \frac{21k-2}{2 \times k} FL$$
$$FLmax = \frac{21k-2}{20k} FL \times 11$$

Therefore, the minimum baud rate that can be received at the transfer destination is as follows.

$$\mathsf{BRmin} = (\mathsf{FLmax}/11)^{-1} = \frac{20\mathsf{k}}{21\mathsf{k} - 2}$$
 Brate

The allowable baud rate error of UARTBn and the transfer destination can be obtained as follows from the expressions described above for computing the minimum and maximum baud rate values.

Division Ratio (k)	Maximum Allowable Baud Rate Error	Minimum Allowable Baud Rate Error
4	+2.33 %	-2.44

- Remarks 1. The reception precision depends on the number of bits in one frame, the base clock frequency, and the division ratio (k). The higher the base clock frequency and the larger the division ratio (k), the higher the precision.

#### (5) Transfer rate during continuous transmission

During continuous transmission, the transfer rate from a stop bit to the next start bit is extended two clocks longer than normal. However, on the reception side, the transfer result is not affected since the timing is initialized by the detection of the start bit.

Representing the 1-bit data length by FL, the stop bit length by FLstp, and the base clock frequency by fx/4 (fx: main clock) yields the following equation.

FLstp = FL + 2/(fx/4)

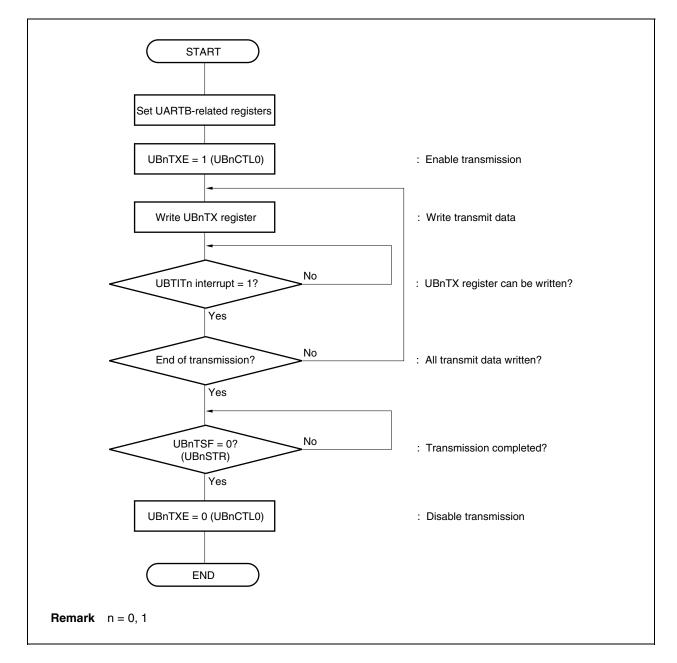

Therefore, the transfer rate during continuous transmission is as follows.

Transfer rate =  $11 \times FL + 2/(fx/4)$

- 3. In the pending mode (UBnITM bit of the UBnFIC0 register = 0), write as many transmit data as the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register to transmit FIFOn. In the pointer mode (UBnITM bit = 1), reference the UBnTB4 to UBnTB0 bits of the UBnFIS1 register and write as many data as the number of vacant bytes in transmit FIFOn to transmit FIFOn.

To fully use the 8-bit  $\times$  16-stage FIFO function, write 16-byte data.

#### 10.2.9 Cautions

When the supply of clocks to UARTBn is stopped (for example, IDLE or STOP mode), operation stops with each register retaining the value it had immediately before the supply of clocks was stopped. The TXDn pin output also holds and outputs the value it had immediately before the supply of clocks was stopped. However, operation is not guaranteed after the supply of clocks is restarted. Therefore, after the supply of clocks is restarted, the circuits should be initialized by setting UBnPWR = 0, UBnRXE = 0, and UBnTXE = 0.

#### 10.3.2 Configuration

CSI3n is controlled by the clocked serial interface mode register 3n (CSIM3n) (n = 0, 1).

(1) Clocked serial interface mode registers 30, 31 (CSIM30, CSIM31)

The CSIM3n register is an 8-bit register for specifying the operation of CSI3n.

(2) Clocked serial interface clock select registers 30, 31 (CSIC30, CSIC31)

The CSIC3n register is an 8-bit register for controlling the operation clock and operating mode of CSI3n.

# (3) Serial I/O shift registers 0, 1 (SIO0, SIO1)

The SIOn register is an 8-bit register for converting between serial data and parallel data. SIOn is used for both transmission and reception.

Data is shifted in (reception) or shifted out (transmission) beginning at either the MSB side or the LSB side.

# (4) Receive data buffer registers 30, 31 (SIRB30, SIRB31)

The SIRB3n register is a 16-bit buffer register that stores receive data. This register is also divided into two registers: the higher 8 bits (SIRB3nH) and lower 8 bits (SIRB3nL).

# (5) Transmit data CSI buffer registers 30, 31 (SFDB30, SFDB31)

The SFDB3n register is a 16-bit buffer register that stores transmit data. This register is also divided into two registers: the higher 8 bits (SFDB3nH) and lower 8 bits (SFDB3nL).

# (6) CSIBUF status registers 30, 31 (SFA30, SFA31)

The SFA3n register is an 8-bit register that indicates the status of CSI data buffer register n (CSIBUFn) or the transfer status.

# (7) Transfer data length select registers 30, 31 (CSIL30, CSIL31)

The CSIL3n register is an 8-bit register that selects the CSI3n transfer data length.

# (8) Transfer data number specification registers 30, 31 (SFN30, SFN31)

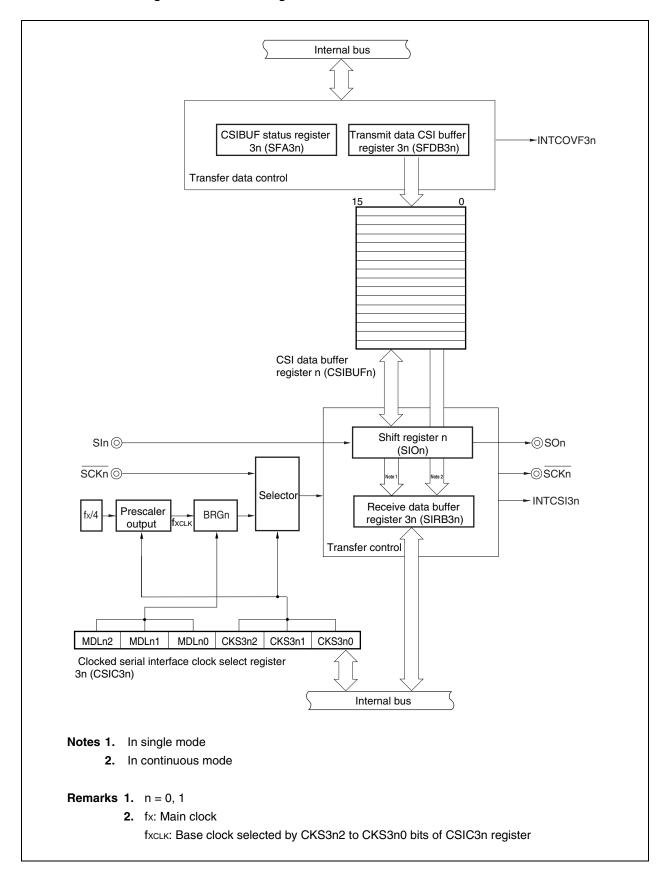

The SFN3n register is an 8-bit register that sets the number of CSI3n transfer data in continuous mode.

# (9) CSI data buffer registers 0, 1 (CSIBUF0, CSIBUF1)

By consecutively writing transmit data to the SFDB3n register from where it is transferred, the data can be stored in the CSIBUFn register while the CSIBUFn pointer for writing is automatically incremented (CSIBUFn).

The CSIBUFn is a 16-bit buffer register.

In the continuous mode, the data received in the CSIBUFn register can be sequentially read while the read CSIBUFn pointer is automatically incremented, by continuously reading the receive data from the SIRB3n register.

# 10.3.3 Control registers

 $\star$ 

Because CSI30 shares pins with UARTB0, the CSI30 mode must be set in advance by using the PMC1 and PFC1 registers (see **10.1.1 Switching between UARTB0 and CSI30 modes**).

# (1) Clocked serial interface mode registers 30, 31 (CSIM30, CSIM31)

The CSIM3n register controls the operation of CSI3n (n = 0, 1). These registers can be read or written in 8-bit or 1-bit units. Be sure to clear bit 0 to 0. If it is set to 1, the operation is not guaranteed.

# Cautions 1. Writing the TRMDn, DIRn, CSITn, and CSWEn bits is enabled only when CTXEn bit = 0 and CRXEn bit = 0.

2 To use CSI3n, be sure to set the external pins related to the CSI3n function to control the mode. Then set the CSICAEn bit to 1 before setting the other bits.

**Note** If the CKPn bit is set to 1 in the master mode (CKS3n2 to CKS3n0 bits are other than 111), the SCKn pin outputs a low level when it is inactive. If the CTXEn bit of the CSIM3n register is cleared to 0 (disabling transmission) and CRXEn bit is cleared to 0 (disabling reception), the SCKn pin outputs a high level.

Therefore, take the following measures to fix the SCKn pin to low level when CSI3n is not used.

#### [SCK0 pin (SCK1 pin)]

- <1> Clearing the P11 bit of the P1 register to 0 (clearing the P23 bit of the P2 register to 0): The port output level is set to low.
- <2> Clearing the PM11 bit of the PM1 register to 0 (clearing the PM23 bit of the PM2 register to 0): The port is set in the output mode.
- <3> Clearing the PMC11 bit of the PMC1 register to 0 (clearing the PMC23 bit of the PMC2 register to 0):

The pin is set in the port mode (fixed to low-level output).

- <4> Clearing the CTXE0 and CRXE0 bits of the CSIM30 register to 0 (clearing the CTXE1 and CRXE1 bits of the CSIM31 register to 0): Transmission and reception are disabled.
- <5> Setting the CTXE0 or CRXE0 bit of the CSIM30 register to 1 (setting the CTXE1 or CRXE1 bit of the CSIM31 register to 1): Transmission or reception is enabled (both transmission and reception can also be enabled).
- <6> Setting the PMC11 bit of the PMC1 register to 1 (setting the PMC23 bit of the PMC2 register to 1): The pin is set in the control mode (SCK0 and SCK1 pin output).

# (3) Receive data buffer registers 30, 31 (SIRB30, SIRB31)

The SIRB3n register is a 16-bit buffer register that stores receive data.

By consecutively reading this register in the continuous mode (TRMDn bit = 1 in the CSIM3n register), the received data in the CSIBUFn register can be sequentially read while the CSIBUFn pointer for reading is incremented.

In the single mode (TRMDn bit = 0 in the CSIM3n register), received data is read by reading the SIRB3n register and it is judged that the SIRB3n register has become empty.

The SIRB3n register is read-only, in 16-bit units.

When the higher 8 bits of the SIRB3n register are used as the SIRB3nH register and the lower 8 bits as the SIRB3nL register, these registers are read-only, in 8-bit units. When reading in 8-bit units, be sure to read the SIRB3nH register and SIRB3nL register in that order.

# (4) Transmit data CSI buffer registers 30, 31 (SFDB30, SFDB31)

The SFDB3n register is a 16-bit buffer register that stores transmit data.

When transmit data is written to this register, the data is sequentially stored in the CSIBUFn register while the CSIBUFn pointer for writing is incremented.

When the data of this register is read, the value of the transmit data written last is read.

The SFDB3n register can be read or written in 16-bit units.

When the higher 8 bits of the SFDB3n register are used as the SFDB3nH register, and the lower 8 bits as the SFDB3nL register, these registers can be read or written in 8-bit units. When reading in 8-bit units, be sure to read the SFDB3nH register and SFDB3nL register in that order.

# (5) CSIBUF status registers 30, 31 (SFA30, SFA31)

These registers indicate the status of the CSIBUFn register or the transfer status.

These registers can be read or written in 8-bit or 1-bit units (however, bits 6 to 0 can only be read. They do not change even if they are written).

- Cautions 1. Reading the SFA3n register is prohibited when the CSICAEn bit of the CSIM3n register is 1 and when the main clock (fx) is stopped.
  - 2. Because the values of the SFFULn, SFEMPn, CSOTn, and SFPn3 to SFPn0 bits may change at any time during transfer, their values during transfer may differ from the actual values. Especially, use the CSOTn bit independently (do not use this bit in relation with the other bits). To detect the end of transfer by the SFA3n register, check to see if the SFEMPn bit is 1 after the data to be transferred has been written to the CSIBUFn register.
  - 3. If the SFA3n register is read immediately after data has been written to the SFDB3n and SFDB3nL registers when the main clock (fx) is 84 MHz or lower, the values of the SFFULn, SFEMPn, and SFPn3 to SFPn0 bits do not change in time.
  - 4. If the SFA3n register is read before the SFFULn bit is set to 1 and the 17th data is written, the CSIBUFn overflow interrupt (INTCOVF3n) is generated.

This bit is always 0 when it is read.         2. If 1 is written to the FPCLRn bit in the middle of transfer, transfer is aborted. Because all the CSIBUFn pointers are cleared to 0, the remaining data in the CSIBUFn register is ignored.         If 1 is written to the FPCLRn bit, be sure to read the SFA3n register to check to see if all the CSIBUFn pointers have been correctly cleared to 0 (SFFULn bit = 0, SFEMPn bit = 1, SFPn3 to SFPn0 bits = 0000).         Nothing happens even if 0 is written to the FPCLRn bit.

# (6) Transfer data length select registers 30, 31 (CSIL30, CSIL31)

The CSIL3n register is used to select the transfer data length of CSI3n. These registers can be read or written in 8-bit or 1-bit units. Be sure to clear bits 7 to 4 to 0. If they are set to 1, the operation is not guaranteed.

# Caution The CSIL3n register may be transferring data when the CTXEn or CRXEn bit of the CSIM3n register is 1. Before writing data to the CSIL3n register, be sure to clear the CTXEn and CRXEn bits to 0.

These registers can be read or written in 8-bit or 1-bit units.

# 10.3.4 Dedicated baud rate generators 0, 1 (BRG0, BRG1)

The transfer clock of CSI3n can be selected from the output of a dedicated baud rate generator or external clock (n = 0, 1).

The serial clock source is specified by the CSIC3n register.

In the master mode (CKS3n2 to CKS3n0 bits = other than 111 in the CSIC3n register), BRGn is selected as the clock source.

# (2) Function of CSI data buffer registers 0, 1 (CSIBUF0, CSIBUF1)

By consecutively writing the transmit data to the SFDB3n register from where it is transferred, the data can be stored in the CSIBUFn register while the CSIBUFn pointer for writing is automatically incremented (the CSIBUFn register size is 16 bits  $\times$  16) (n = 0, 1).

The condition under which transfer is to be started (SFEMPn bit = 0 in the SFA3n register) is satisfied when data is written to the lower 8 bits (SFDB3nL register) of the SFDB3n register. If a transfer data length of 9 bits or more is specified (CCLn3 to CCLn0 bits = 0000 or 1001 to 1111 in the CSIL3n register), data must be written to the SFDB3n register in 16-bit units or to the SFDB3nH and SFDB3nL registers, in that order, in 8-bit units. If the transfer data length is set to 8 bits (CCLn3 to CCLn0 bits = 1000 in the CSIL3n register), data must be written to the SFDB3nL register in 8-bit units or to the SFDB3n register in 16-bit units. (If data is written to the SFDB3nL register in 8-bit units or to the SFDB3n register in 16-bit units. (If data is written to the SFDB3nL register in 16-bit units, however, the higher 8 bits of the data (of the SFDB3nH register) are ignored and not transferred).

The SFFULn bit of the SFA3n register is set to 1 when 16 data exist in the CSIBUFn register and outputs a CSIBUFn overflow interrupt (INTCOVF3n) when the SFFULn bit = 1 and when the 17th transfer data is written.

Sixteen data exist in the CSIBUFn register in the single mode (TRMDn bit = 0 in the CSIM3n register) when "CSIBUFn pointer value for Writing = CSIBUFn pointer value for SIOn loading, and SFFULn bit = 1 in the SFA3n register". When the CSIBUFn pointer for SIOn loading is incremented after completion of transfer, the CSIBUFn register has a vacancy of one data (in the continuous mode (TRMDn bit = 1 in the CSIM3n register), the CSIBUFn register does not have a vacancy even if one data has been transferred).

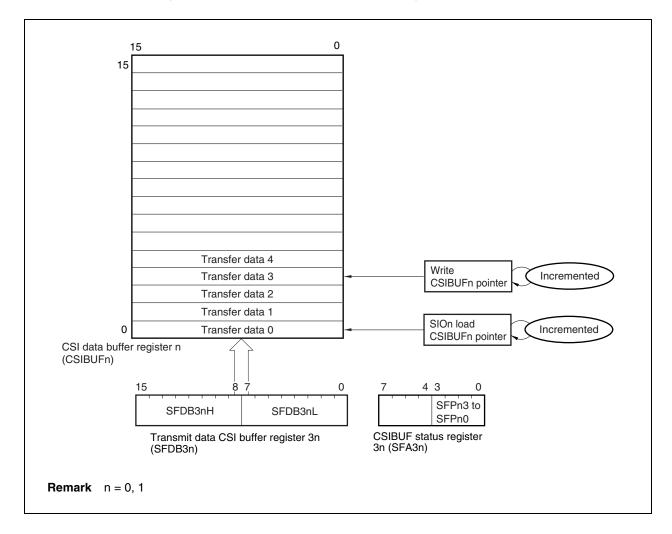

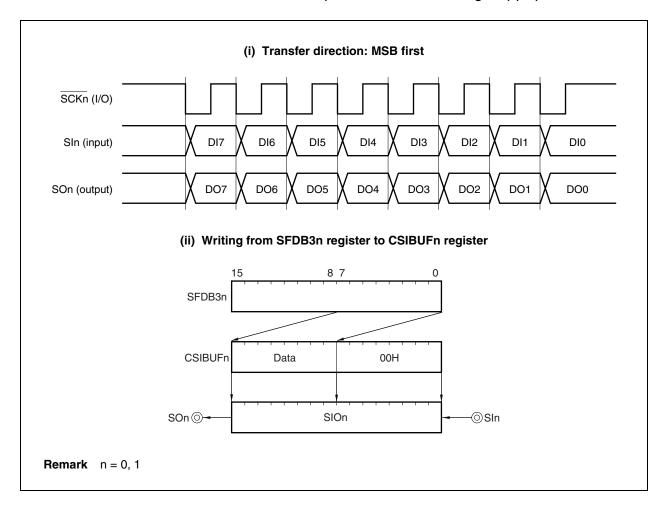

Figure 10-24. Function of CSI Data Buffer Register n (CSIBUFn)

# (3) Data transfer direction specification function

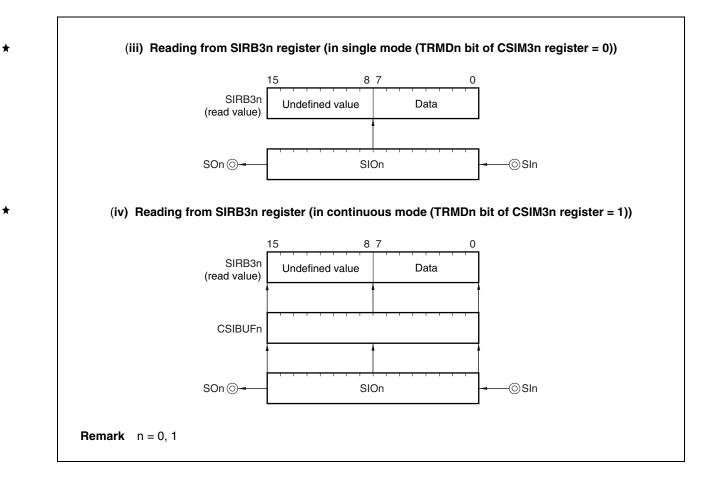

The data transfer direction can be changed by using the DIRn bit of the CSIM3n register (n = 0, 1).

The transfer data length can be set from 8 to 16 bits in 1-bit units, by using the CCLn3 to CCLn0 bits of the CSIL3n register (n = 1, 0).

# (5) Function to select serial clock and data phase

The serial clock and data phase can be changed by using the CKPn and DAPn bits of the CSIC3n register (n = 0, 1).

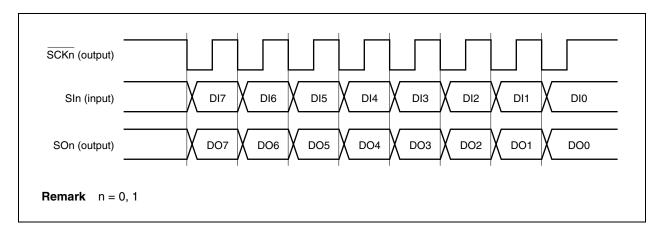

# (6) Master mode

The master mode is set and data is transferred with the transfer clock output to the  $\overline{SCKn}$  pin when the CKS3n2 to CKS3n0 bits of the CSIC3n register are set to a value other than 111 ( $\overline{SCKn}$  pin input is invalid) (n = 0, 1).

The default output level of the  $\overline{SCKn}$  pin is high when the CKPn bit of the CSIC3n register is 0, and low when the CKPn bit is 1.

# (7) Slave mode

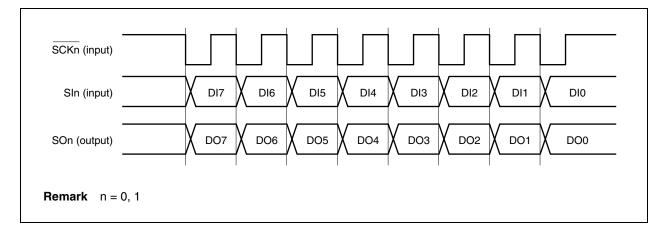

\*

\*

The slave mode is set when the CKS3n2 to CKS3n0 bits of the CSIC3n register are set to 111, and data is transferred with the transfer clock input to the  $\overline{SCKn}$  pin (in the slave mode, it is recommended to set the MDLn2 to MDLn0 bits of the CSIC3n register to 000 and set the BRGn stop mode) (n = 0, 1).

# Figure 10-30. Slave Mode (CKPn and DAPn Bits = 00 in CSIC3n Register,

The conditions under which data can be transferred in the slave mode are listed in the table below.

# (8) Transfer clock selection function

In the master mode (CKS3n2 to CKS3n0 bits = other than 111 in the CSIC3n register), the bit transfer rate can be selected by setting the CKS3n2 to CKS3n0 and MDLn2 to MDLn0 bits of the CSIC3n register (see **10.3.3 (2) Clocked serial interface clock select registers 30, 31 (CSIC30, CSIC31)**).

# (9) Single mode

The single mode is set when the TRMDn bit of the CSIM3n register is 0 (n = 0, 1).

In this mode, transfer is started when the CTXEn bit or CRXEn bit is set to 1 and when data is in the CSIBUFn register (SFEMPn bit = 0 in the SFA3n register).

If no data is in the CSIBUFn register (SFEMPn bit = 1), transfer is kept waiting until transmit data or dummy data is written to the SFDB3n register.

When data is transferred to the CSIBUFn register while transmission or reception is enabled (CTXEn or CRXEn bit is 1), the CSOTn bit of the SFA3n register (transfer status flag) is set to 1. If transfer is not in the wait status, the transfer data indicated by the SIOn load CSIBUFn pointer is loaded from the CSIBUFn register to the SIOn register, and transfer processing is started.

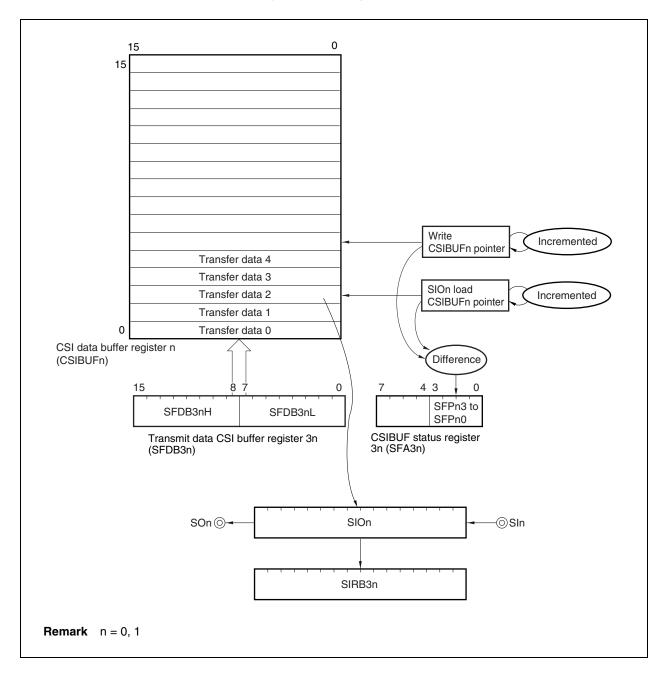

If the SIRB3n register is empty when one data has been transferred in the reception mode or transmission/reception mode, the received data is stored from the SIOn register to the SIRB3n register, the transmission/reception completion interrupt (INTCSI3n) is output, and the SIOn load CSIBUFn pointer is incremented. If transmit data or dummy data is stored in the CSIBUFn register, the next transfer processing is started. However, storing the receive data in the SIRB3n register, outputting the INTCSI3n interrupt, and incrementing the SIOn load CSIBUFn pointer are held pending, until the previously received data is read from the SIRB3n register and the SIRB3n register becomes empty.

In the transmission mode, the INTCSI3n interrupt is output and the SIOn load pointer is incremented when transfer processing of one data has been completed (the SIRB3n register is always empty because no data is stored from the SIOn register to the SIRB3n register).

In all modes (transmission, reception, and transmission/reception modes), if the CSIBUFn register is empty (write CSIBUFn pointer value = SIOn load CSIBUFn pointer value) when transfer processing of one data has been completed, the CSOTn bit is cleared to 0. The value of the "number of remaining data in the CSIBUFn register (write CSIBUFn pointer – SIOn load pointer)" can always be read from the SFPn3 to SFPn0 bits of the SFA3n register.

Caution When writing data to the SFDB3n register, be sure to confirm that the SFFULn bit of the SFA3n register is 0. Even if data is written to this register when SFFULn bit is 1, the CSIBUFn overflow interrupt (INTCOVF3n) is output, and the written data is ignored.

# (10)Continuous mode

The continuous mode is set when the TRMDn bit of the CSIM3n register is 1 (n = 0, 1).

In this mode, transfer is started when the CTXEn bit or CRXEn bit is 1 and when data is in the CSIBUFn register (SFEMPn bit = 0 in the SFA3n register). At this time, set the number of transfer data in advance by using the SFNn3 to SFNn0 bits of the SFN3n register. If 17 or more transfer data are written to the CSIBUFn register, the excess data are ignored and not transferred. Do not write data exceeding the number of transfer data specified by the SFNn3 to SFNn0 bits of the SFN3n register to the CSIBUFn register.

If no data is in the CSIBUFn register (SFEMPn bit = 1), transfer is kept waiting until transmit data or dummy data is written to the SFDB3n register.

If data is transferred to the CSIBUFn register when transmission or reception is enabled (CTXEn or CRXEn bit is 1), the CSOTn bit (transfer status flag) of the SFA3n register is set to 1 and the transfer data indicated by the SIOn load/store CSIBUFn pointer is loaded from the CSIBUFn register to SIOn register. Then transfer processing is started.

When transfer processing of one data is completed in the reception mode or transmission/reception mode, the received data is overwritten from the SIOn register to the transfer data in the CSIBUFn register indicated by the SIOn load/store CSIBUFn pointer, and then the pointer is incremented. By consecutively reading the transfer data from the SIRB3n register after all data in the CSIBUFn register have been transferred (when the INTCSI3n interrupt has occurred), the receive data can be sequentially read while the read CSIBUFn pointer is incremented.

In the transmission mode, the SIOn load/store CSIBUFn pointer is incremented when transfer processing of one data has been completed.

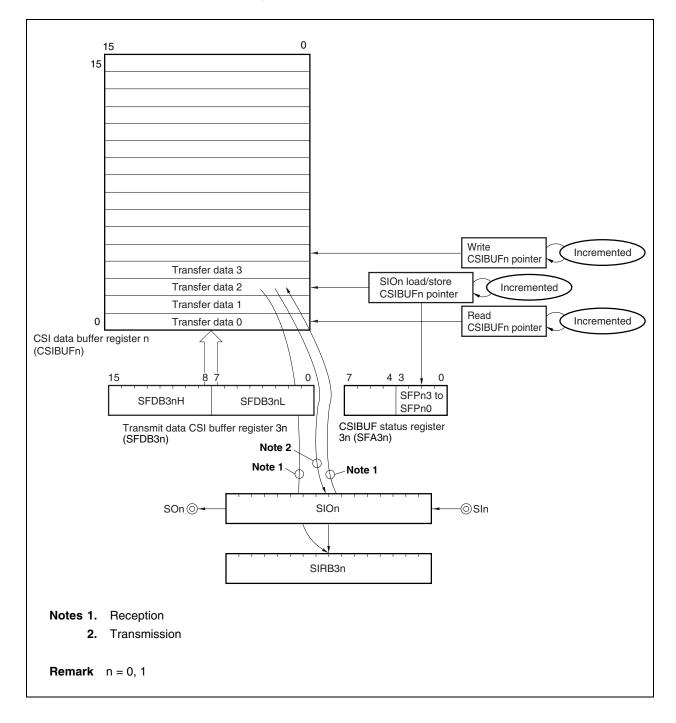

In all modes (transmission, reception, and transmission/reception modes), when data has been transferred by the value set by the SFNn3 to SFNn0 bits of the SFN3n register, the CSOTn bit is cleared to 0 and the transmission/reception completion interrupt (INTCSI3n) is output.

To transfer the next data, be sure to write 1 to the FPCLRn bit of the SFA3n register and clear all the CSIBUFn pointers to 0.

The "number of transferred data (SIOn load/store CSIBUFn pointer value)" can always be read from the SFPn3 to SFPn0 bits of the SFA3n register.

Caution The SFA3n register is in the same status when transfer data is written (before start of transfer) after the CSIBUFn pointer is cleared (FPCLRn bit = 1 in the SFA3n register) and when 16 data have been transferred (SFFULn bit = 0, SFEMPn bit = 1, SFPn3 to SFPn0 bits = 0000 in the SFA3n register).

×

#### (11)Transmission mode

\*

The transmission mode is set when the CTXEn bit of the CSIM3n register is set to 1 and the CRXEn bit is cleared to 0. In this mode, transmission is started by a trigger that writes transmit data to the SFDB3n register or sets the CTXEn bit to 1 when transmit data is in the CSIBUFn register (n = 0, 1). Even in the single mode (TRMDn bit = 0 in the CSIM3n register), whether the SIRB3n or SIOn register is empty has nothing to do with starting transmission. The value input to the SIn pin during transmission is latched in the shift register (SIOn) but is not transferred to the SIRB3n and CSIBUFn registers at the end of transmission. The transmission/reception completion interrupt (INTCSI3n) occurs immediately after data is sent out from the SIOn register.

#### (12) Reception mode

The reception mode is set when the CTXEn bit of the CSIM3n register is cleared to 0 and CRXEn bit is set to 1. In this mode, reception is started by using the processing of writing dummy data to the SFDB3n register as a trigger (n = 0, 1). In the single mode (TRMDn bit = 0 in the CSIM3n register), however, the condition of starting reception includes that the SIRB3n or SIOn register is empty. (If reception to the SIOn register is completed when the previously received data is held in the SIRB3n register without being read, the previously received data is read from the SIRB3n register and the wait status continues until the SIRB3n register becomes empty.) In the continuous mode, reception starts by writing dummy data of the number of receive data to the SFDB3n register with the first dummy data write processing taken as a trigger.

The SOn pin outputs a low level.

The transmission/reception completion interrupt (INTCSI3n) occurs immediately after receive data is transferred from the SIOn register to the SIRB3n register.

#### (13) Transmission/reception mode

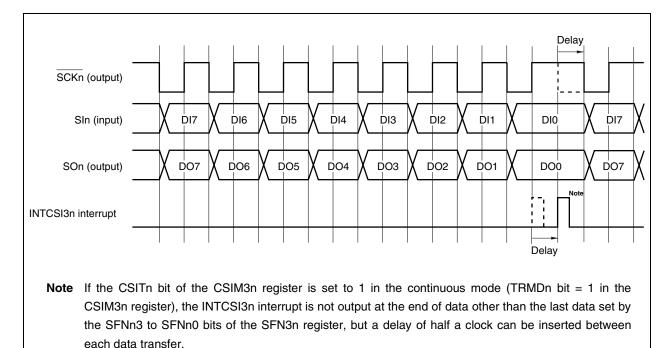

The transmission/reception mode is set when both the CTXEn and CRXEn bits of the CSIM3n register are set to 1. In this mode, transmission/reception is started by using the processing to write transmit data to the SFDB3n register as a trigger (n = 0, 1). In the single mode (TRMDn bit = 0 in the CSIM3n register), however, the condition of starting transmission/reception includes that the SIRB3n or SIOn register is empty. (If reception to the SIOn register is completed when the previously received data is held in the SIRB3n register without being read, the previously received data is read from the SIRB3n register and the wait status continues until the SIRB3n register becomes empty.)

# (14) Delay control of transmission/reception completion interrupt (INTCSI3n)

In the master mode (CKS3n2 to CKS3n0 bits = other than 111 in the CSIC3n register), occurrence of the transmission/reception completion interrupt (INTCSI3n) can be delayed by half a clock (1/2 serial clock), depending on the setting (1) of the CSITn bit of the CSIM3n register. The CSITn bit is valid only in the master mode. In the slave mode (CKS3n2 to CKS3n0 bits = 111 in the CSIC3n register), setting the CSITn bit to 1 is prohibited (even if set, the INTCSI3n interrupt is not affected).

Caution If the CSITn bit of the CSIM3n register is set to 1 in the continuous mode (TRMDn bit = 1 in the CSIM3n register), the INTCSI3n interrupt is not output at the end of data other than the last data set by the SFNn3 to SFNn0 bits of the SFN3n register, but a delay of half a clock can be inserted between each data transfer.

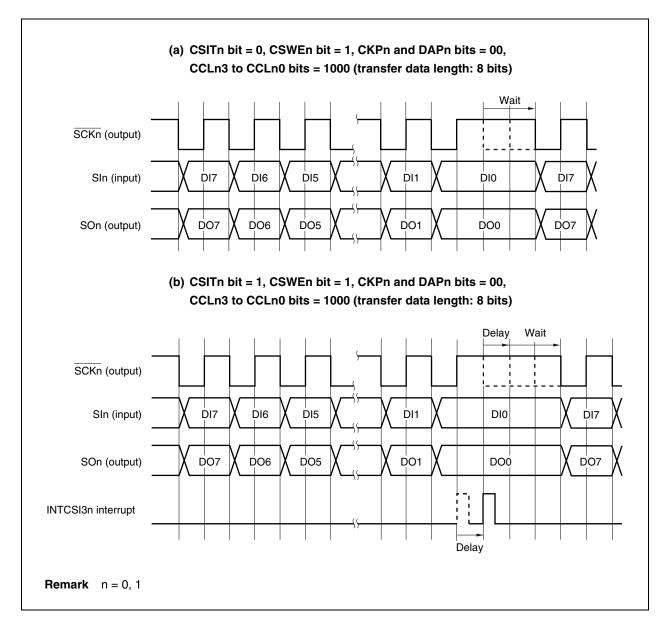

Figure 10-33. Delay Control of Transmission/Reception Completion Interrupt (INTCSI3n): CSITn Bit = 1 in CSIC3n Register, CSWEn Bit = 0, CKPn and DAPn Bits = 00, CCLn3 to CCLn0 Bits = 1000 in CSIL3n Register (Transfer Data Length: 8 Bits)

**Remark** n = 0, 1

# (15) Enabling/disabling transfer wait

In the master mode (CKS3n2 to CKS3n0 bits = other than 111 in the CSIC3n register), starting transfer can be delayed by one clock, depending on the setting (1) of the CSWEn bit of the CSIM3n register (CSWEn bit = 1 (transfer wait inserted)). The CSWEn bit is valid only in the master mode. In the slave mode (CKS3n2 to CKS3n0 bits = 111 in the CSIC3n register), setting the CSWEn bit to 1 is prohibited (even if set, transfer wait is not inserted).

# (16)Output pins

\*

# (a) SCKn pin

The  $\overline{SCKn}$  pin outputs a high level when both the CTXEn and CRXEn bits of the CSIM3n register are 0 (n = 0, 1).

In the master mode (CKS3n2 to CKS3n0 bits = other than 111 in the CSIC3n register), this pin outputs the default level when the FPCLRn bit of the SFA3n register is set to 1.

Table 10-8. Default Output Level of SCKn Pin

CKPn Bit	CKS3n2 to CKS3n0 Bits	Default Output Level of SCKn Pin
0	111 (slave mode)	High level <sup>Note</sup>
	Other than 111 (master mode)	High level
1	111 (slave mode)	– (input)
	Other than 111 (master mode)	Low level

Note Default value after reset or value when CSICAEn bit = 0 in the CSIM3n register

**Remarks 1.** The output of the SCKn pin changes if the CKPn bit is rewritten in the master mode. **2.** n = 0, 1

## (b) SOn pin

The SOn pin outputs a low level when both the CTXEn and CRXEn bits of the CSIM3n register are 0 (n = 0, 1).

This pin outputs a low level when the FPCLRn bit of the SFA3n register is 1 (the previous value is retained only in the slave mode (CKS3n2 to CKS3n0 bits = 111 in the CSIC3n register) and when the DAPn bit = 0 in the CSIC3n register).

#### Table 10-9. Default Output Level of SOn Pin

Default Output Level of SOn Pin

Note Default value after reset or value when CSICAEn bit = 0 in the CSIM3n register

#### **Remark** n = 0, 1

# (17) CSIBUFn overflow interrupt signal (INTCOVF3n)

The INTCOVF3n interrupt is output when 16 data exist in the CSIBUFn register and when the 17th data is written (to the SFDB3n or SFDB3nL register) (the 17th data is not written but ignored).

In the single mode (TRMDn bit = 0 in the CSIM3n register), 16 data exist in the CSIBUFn register when "write CSIBUFn pointer value = SIOn load CSIBUFn pointer value and SFFULn bit = 1 in the SFA3n register". When transfer is completed and the SIOn load CSIBUFn pointer is incremented, the CSIBUFn register has one vacancy (the CSIBUFn register has no vacancy even when transfer of one data has been completed in the continuous mode (TRMDn bit = 1 in the CSIM3n register)).

# 10.3.6 Usage

# (1) Single mode (in master mode and transmission mode)

- <1> Set the external pins related to the CSI3n function to control mode.
- <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
- <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
- <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
- <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable transmission by setting the CTXEn bit to 1.
- <7> Confirm that the SFFULn bit of the SFA3n register is 0, and then write transfer data to the SFDB3n register. If it is clearly known that the SFFULn bit is 0 because transfer data is written to that bit by the interrupt servicing routine of INTCSI3n, it is not always necessary to confirm that the SFFULn bit is 0.
- <8> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit of the SFA3n register is 1, and disable transmission by clearing the CTXEn bit of the CSIM3n register to 0 (end of transmission).

#### Caution To execute further transfer, repeat <7> before <8>.

## (2) Single mode (in master mode and reception mode)

- <1> Set the external pins related to the CSI3n function to control mode.
  - <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
  - <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
  - <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
  - <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
  - <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable reception by setting the CRXEn bit to 1.
  - <7> Confirm that the SFFULn bit of the SFA3n register is 0, and then write dummy transfer data to the SFDB3n register (reception start trigger). If it is clearly known that the SFFULn bit is 0 because dummy transfer data is written to that bit by the interrupt servicing routine of INTCSI3n, it is not always necessary to confirm that the SFFULn bit is 0.
  - <8> Confirm that the INTCSI3n interrupt has occurred, and then read the SIRB3n register.
  - <9> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit is 1, and disable reception by clearing the CRXEn bit of the CSIM3n register to 0 (end of reception).

#### Cautions 1. To execute further transfer, repeat <7> and <8> before <9>.

2. The SOn pin outputs a low level but this is invalid.

# 10.3.7 Cautions

The following points must be noted when using CSI3n (n = 0, 1).

- The CSI3n unit is reset and CSI3n is stopped when the CSICAEn bit of the CSIM3n register is cleared to 0. To operate CSI3n, first set the CSICAEn bit to 1. Usually, before clearing the CSICAEn bit to 0, clear both the CTXEn and CRXEn bits to 0 (after the end of transfer).
- (2) Be sure to write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0 before enabling transfer by setting the CTXEn or CRXEn bit of the CSIM3n register to 1. If the CTXEn or CRXEn bit is set to 1 without clearing the pointers, and if the previously transferred data remains in the CSIBUFn register, transferring that data is immediately started.

If transfer data is set to the CSIBUFn register before transfer is enabled, transfer is started as soon as the CTXEn or CRXEn bit is set to 1.

(3) If the SFA3n register is read immediately after data has been written to the SFDB3n and SFDB3nL registers when the main clock (fx) is used at 84 MHz or lower, the SFFULn, SFEMPn, and SFPn3 to SFPn0 bits of the SFA3n register may not change their values in time.

If the SFA3n register is read before the SFFULn bit is set to 1 and a 17th data is written, the CSIBUFn overflow interrupt (INTCOVF3n) occurs.

# CHAPTER 11 USB FUNCTION CONTROLLER (USBF)

The V850E/ME2 has an internal USB function controller (USBF) conforming to the Universal Serial Bus Specification.

# 11.1 Overview

\*

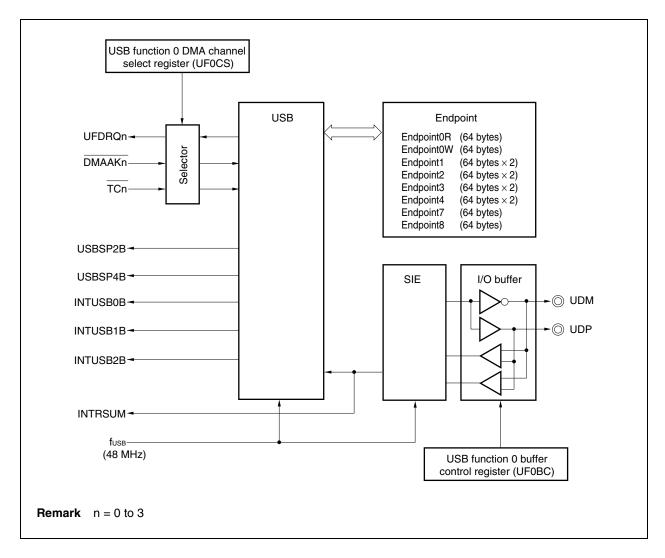

- Conforms to the Universal Serial Bus Specification.
- Supports 12 Mbps (full-speed) transfer
- Endpoint for transfer incorporated

Endpoint Name	FIFO Size (Bytes)	Transfer Type	Remark
Endpoint0 Read	64	Control transfer	-
Endpoint0 Write	64	Control transfer	-
Endpoint1	64×2	Bulk 1 transfer (IN)	2-buffer configuration
Endpoint2	64×2	Bulk 1 transfer (OUT)	2-buffer configuration
Endpoint3	64 × 2	Bulk 2 transfer (IN)	2-buffer configuration
Endpoint4	64 × 2	Bulk 2 transfer (OUT)	2-buffer configuration
Endpoint7	8	Interrupt 1 transfer	_
Endpoint8	8	Interrupt 2 transfer	_

• Clock: Clock input from UCK pin (fuse = 48 MHz)

Caution When using the USB function, be sure to set (1) the UCKCNT bit of the UCKC register. If the registers related to the USB function while the UCKCNT bit is 0, 0 is read.

- **Notes 1.** If the wLength value is less than the prepared value, the wLength value is returned; if the wLength value is greater than the prepared value, the prepared value is returned.
  - 2. The CLEAR\_FEATURE request clears UF0 device status register L (UF0DSTL) and UF0 EPn status register L (UF0EnSL) (n = 0 to 4, 7, 8) when ACK is received in the status stage.

**Remark**  $\sqrt{}$ : Data stage is provided

×: Data stage is not provided

- **Notes 3.** The SET\_FEATURE request sets the UF0 device status register L (UF0DSTL) and UF0 EPn status register L (UF0EnSL) (n = 0 to 4, 7, 8) when ACK is received in the status stage. If the E0HALT bit of the UF0E0SL register is set, a STALL response is made in the status stage or data stage of control transfer for a request other than the GET\_STATUS Endpoint0 request, SET\_FEATURE Endpoint0 request, and a request generated by the CPUDEC interrupt request, until the CLEAR\_FEATURE Endpoint0 request is received. A STALL response to an unsupported request does not set the E0HALT bit of the UF0E0SL register to 1, and the STALL response is cleared as soon as the next SETUP token has been received.
  - 4. If the wValue is not the default value, an automatic STALL response is made.
- Cautions 1. The sequence of control transfer defined by the Universal Serial Bus Specification is not satisfied under the following conditions. The operation is not guaranteed under these conditions.
  - If an IN/OUT token is suddenly received without a SETUP stage
  - If DATA PID1 is sent in the data phase of the SETUP stage
  - If a token of 128 addresses or more is received
  - If the request data transmitted in the SETUP stage is of less than 8 bytes
  - 2. An ACK response is made even when the host transmits data other than a Null packet in the status stage.
  - 3. If the wLength value is 00H during control transfer (read) of FW processing, a Null packet is automatically transmitted for control transfer (without data). The FW request does not automatically transmit a Null packet.
- Remarks 1. Df: Default state, Ad: Addressed state, Cf: Configured state
  - **2.** n = 0 to 4

It is determined by the setting of the UF0 active interface number register (UF0AIFN) whether a request with Interface number 1 to 4 is correctly responded to, depending on whether the Interface number of the target is valid or not.

- \$\$: Valid Endpoint number including transfer direction
   The valid Endpoint is determined by the currently set Alternate Setting number (see 11.4 (36) UF0 active alternative setting register (UF0AAS), (38) UF0 endpoint 1 interface mapping register (UF0E1IM) to (43) UF0 endpoint 8 interface mapping register (UF0E8IM)).
- 4. ? and #: Value transmitted from host (information on Interface numbers 0 to 4) It is determined by the UF0 active interface number register (UF0AIFN) and UF0 active alternative setting register (UF0AAS) whether an Alternate Setting request corresponding to each Interface number is correctly responded to or not, depending on whether the Interface number and Alternate Setting of the target are valid or not.

#### (2) Processing

The processing of an automatic request in the Default state, Addressed state, and Configured state is described below.

**Remark** Default state: State in which an operation is performed with the Default address Addressed state: State after an address has been allocated Configured state: State after SET\_CONFIGURATION wValue = 1 has been correctly received

#### (a) CLEAR\_FEATURE() request

A STALL response is made in the status stage if the CLEAR\_FEATURE() request cannot be cleared, if FEATURE does not exist, or if the target is an interface or an endpoint that does not exist. A STALL response is also made if the wLength value is other than 0.

- Default state: The correct response is made when the CLEAR\_FEATURE() request has been received only if the target is a device or a request for Endpoint0. Otherwise, a STALL response is made in the status stage.
- Addressed state: The correct response is made when the CLEAR\_FEATURE() request has been
   received only if the target is a device or a request for Endpoint0. Otherwise, a STALL
   response is made in the status stage.
- Configured state: The correct response is made when the CLEAR\_FEATURE() request has been received only if the target is a device or a request for an endpoint that exists. Otherwise, a STALL response is made in the status stage.

When the CLEAR\_FEATURE() request has been correctly processed, the corresponding bit of the UF0 CLR request register (UF0CLR) is set to 1, the EnHALT bit of the UF0 EPn status register L (UF0EnSL) is cleared to 0, and an interrupt is issued (n = 0 to 4, 7, 8). If the CLEAR\_FEATURE() request is received when the subject is an endpoint, the toggle bit (that controls switching between DATA0 and DATA1) of the corresponding endpoint is always re-set to DATA0.

#### (b) GET\_CONFIGURATION() request

A STALL response is made in the data stage if any of wValue, wIndex, or wLength is other than the values shown in Table 11-2.

- Default state: The value stored in the UF0 configuration register (UF0CNF) is returned when the GET\_CONFIGURATION() request has been received.
- Addressed state: The value stored in the UF0CNF register is returned when the GET\_CONFIGURATION() request has been received.
- Configured state: The value stored in the UF0CNF register is returned when the GET\_CONFIGURATION() request has been received.

## (c) GET\_DESCRIPTOR() request

If the subject descriptor has a length that is a multiple of wMaxPacketSize, a Null packet is returned to indicate the end of the data stage. If the length of the descriptor at this time is less than the wLength value, the entire descriptor is returned; if the length of the descriptor is greater than the wLength value, the descriptor up to the wLength value is returned.

- Default state: The value stored in UF0 device descriptor register n (UF0DDn) and UF0 configuration/interface/endpoint descriptor register m (UF0CIEm) is returned (n = 0 to 17, m = 0 to 255) when the GET\_DESCRIPTOR() request has been received.
- Addressed state: The value stored in the UF0DDn register and UF0CIEm register is returned when the GET\_DESCRIPTOR() request has been received.
- Configured state: The value stored in the UF0DDn register and UF0CIEm register is returned when the GET\_DESCRIPTOR() request has been received.

A descriptor of up to 256 bytes can be stored in the UF0CIEm register. To return a descriptor of more than 256 bytes, set the CDCGDST bit of the UF0MODC register to 1 and process the GET\_DESCRIPTOR() request by FW.

Store the value of the total number of bytes of the descriptor set by the UF0CIEm register -1 in the UF0 descriptor length register (UF0DSCL). The transfer data is controlled by the value of this data +1 and wLength.

#### (d) GET\_INTERFACE() request

If either of wValue and wLength is other than that shown in Table 11-2, or if wIndex is other than that set by the UF0 active interface number register (UF0AIFN), a STALL response is made in the data stage.

- Default state: A STALL response is made in the data stage when the GET\_INTERFACE() request has been received.
- Addressed state: A STALL response is made in the data stage when the GET\_INTERFACE() request
   has been received.
- Configured state: The value stored in the UF0 interface n register (UF0IFn) corresponding to the wIndex value is returned (n = 0 to 4) when the GET\_INTERFACE() request has been received.

## (e) GET\_STATUS() request

A STALL response is made in the data stage if any of wValue, wIndex, or wLength is other than the values shown in Table 11-2. A STALL response is also made in the data stage if the target is an interface or an endpoint that does not exist.

- Default state: The value stored in the target status register<sup>Note</sup> is returned only when the GET\_STATUS() request has been received and when the request is for a device or Endpoint0. Otherwise, a STALL response is made in the data stage.
- Addressed state: The value stored in the target status register<sup>Note</sup> is returned only when the GET\_STATUS() request has been received and when the request is for a device or Endpoint0. Otherwise, a STALL response is made in the data stage.
- Configured state: The value stored in the target status register<sup>Note</sup> is returned only when the GET\_STATUS() request has been received and when the request is for a device or an endpoint that exists. Otherwise, a STALL response is made in the data stage.

Note The target status register is as follows.

- If the target is a device: UF0 device status register L (UF0DSTL)
- If the target is Endpoint0: UF0 EP0 status register L (UF0E0SL)
- If the target is Endpoint n: UF0 EPn status register L (UF0EnSL) (n = 1 to 4, 7, 8)

#### (f) SET\_ADDRESS() request

A STALL response is made in the status stage if either of windex or wLength is other than the values shown in Table 11-2. A STALL response is also made if the specified device address is greater than 127.

- Default state: The device enters the Addressed state and changes the USB Address value to be input to SIE into a specified address value if the specified address is other than 0 when the SET\_ADDRESS() request has been received. If the specified address is 0, the device remains in the Default state.
- Addressed state: The device enters the Default state and returns the USB Address value to be input to SIE to the default address if the specified address is 0 when the SET\_ADDRESS() request has been received. If the specified address is other than 0, the device remains in the Addressed state, and changes the USB Address value to be input to SIE into a specified new address value.
- Configured state: The device remains in the Configured state and returns the USB Address value to be input to SIE to the default address if the specified address is 0 when the SET\_ADDRESS() request has been received. In this case, the endpoints other than Endpoint0 remain valid, and control transfer (IN), control transfer (OUT), bulk transfer and interrupt transfer for an endpoint other than Endpoint0 are also acknowledged. If the specified address is other than 0, the device remains in the Configured state and changes the USB Address value to be input to SIE into a specified new address value.

#### (g) SET\_CONFIGURATION() request

If any of wValue, wIndex, or wLength is other than the values shown in Table 11-2, a STALL response is made in the status stage.

- Default state: The CONF bit of the UF0 mode status register (UF0MODS) and the UF0 configuration register (UF0CNF) are set to 1 if the specified configuration value is 1 when the SET\_CONFIGURATION() request has been received. If the specified configuration value is 0, the CONF bit of the UF0MODS register and UF0CNF register are cleared to 0. In other words, the device skips the Addressed state and moves to the Configured state in which it responds to the Default address.
- Addressed state: The CONF bit of the UF0MODS register and UF0CNF register are set to 1 and the device enters the Configured state if the specified configuration value is 1 when the SET\_CONFIGURATION() request has been received. If the specified configuration value is 0, the device remains in the Addressed state.
- Configured state: The CONF bit of the UF0MODS register and UF0CNF register are set to 1 and the device returns to the Addressed state if the specified configuration value is 0 when the SET\_CONFIGURATION() request has been received. If the specified configuration value is 1, the device remains in the Configured state.

If the SET\_CONFIGURATION() request has been correctly processed, the target bit of the UF0 SET request register (UF0SET) is set to 1, and an interrupt is issued. All Halt Features are cleared after the SET\_CONFIGURATION() request has been completed even if the specified configuration value is the same as the current configuration value. If the SET\_CONFIGURATION() request has been correctly processed, the data toggle of all endpoints is always initialized to DATA0 again (it is defined that the default status, Alternative Setting 0, is set from when the SET\_CONFIGURATION request is received to when the SET\_INTERFACE request is received).

#### (h) SET\_FEATURE() request

A STALL response is made in the status stage if the SET\_FEATURE() request is for a Feature that cannot be set or does not exist, or if the target is an interface or an endpoint that does not exist. A STALL response is also made if the wLength value is other than 0.

- Default state: The correct response is made when the SET\_FEATURE() request has been received, only if the request is for a device or Endpoint0. Otherwise, a STALL response is made in the status stage.
- Addressed state: The correct response is made when the SET\_FEATURE() request has been received, only if the request is for a device or Endpoint0. Otherwise, a STALL response is made in the status stage.
- Configured state: The correct response is made when the SET\_FEATURE() request has been received, only if the request is for a device or an endpoint that exists. Otherwise, a STALL response is made in the status stage.

When the SET\_FEATURE() request has been correctly processed, the target bit of the UF0 SET request register (UF0SET) and the EnHALT bit of the UF0 EPn status register L (UF0EnSL) are set to 1, and an interrupt is issued (n = 0 to 4, 7, 8).

#### (i) SET\_INTERFACE() request

If wLength is other than the values shown in Table 11-2, if wIndex is other than the value set to the UF0 active interface number register (UF0AIFN), or if wValue is other than the value set to the UF0 active alternative setting register (UF0AAS), a STALL response is made in the status stage.

- Default state: A STALL response is made in the status stage when the SET\_INTERFACE() request has been received.
- Addressed state: A STALL response is made in the status stage when the SET\_INTERFACE() request
   has been received.
- Configured state: Null packet is transmitted in the status stage when the SET\_INTERFACE() request has been received.

When the SET\_INTERFACE() request has been correctly processed, an interrupt is issued. All the Halt Features of the endpoint linked to the target Interface are cleared after the SET\_INTERFACE() request has been cleared. The data toggle of all the endpoints related to the target Interface number is always initialized again to DATA0. When the currently selected Alternative Setting is to be changed by correctly processing the SET\_INTERFACE() request, the FIFO of the endpoint that is affected is completely cleared, and all the related interrupt sources are also initialized.

When the SET\_INTERFACE() request has been completed, the FIFO of all the endpoints linked to the target Interface are cleared. At the same time, Halt Feature and Data PID are initialized, and the related UF0 INT status n register (UF0ISn) is cleared to 0 (n = 0 to 4). (Only Halt Feature and Data PID are cleared when the SET\_CONFIGURATION request has been completed.)

## 11.3.2 Other requests

## (1) Response and processing

The following table shows how other requests are responded to and processed.

## 11.4 Register Configuration

## 11.4.1 Control registers

## (1) UF0 EP0NAK register (UF0E0N)

This register controls NAK of Endpoint0 (except an automatically executed request).

This register can be read or written in 8-bit units (however, bit 0 can only be read).

It takes five USB clocks to reflect the status on this register after the UF0FIC0 and UF0FIC1 registers have been set. If it is necessary to read the status correctly, therefore, separate a write signal that accesses the UF0FIC0 and UF0FIC1 registers from a read signal that accesses the UF0EPS0, UF0EPS1, UF0EPS2, UF0E0N, and UF0EN registers by at least four USB clocks.

While NAK is being transmitted to Endpoint0 Read, Endpoint2, and Endpoint4, a write access to the EP0NKR bit is ignored.

Next, the procedure of a SETUP transaction that uses IN/OUT tokens is explained below.

#### (a) When IN token is used (except a request automatically executed by hardware)

FW should be used to clear the PROT bit of the UF0IS1 register to 0 after receiving the CPUDEC interrupt and before reading data from the UF0E0ST register. Next, perform processing in accordance with the request and, if it is necessary to return data by an IN token, write data to the UF0E0W register. Confirm that the PROT bit of the UF0IS1 register is 0 after writing has been completed, and set the E0DED bit of the UF0DEND register to 1. The hardware sends out data at the first IN token after the EP0NKW bit has been set to 1. If the PROT bit of the UF0IS1 register is 1, it indicates that a SETUP transaction has occurred again before completion of control transfer. In this case, clear the PROTC bit of the UF0IC1 register to 0 and clear the PROT bit of the UF0IS1 register to 0, and then read data from the UF0E0ST register again. A request received later can be read.

#### (b) When OUT token is used (except a request automatically executed by hardware)

FW should be used to clear the PROT bit of the UF0IS1 register after receiving the CPUDEC interrupt and before reading data from the UF0E0ST register. Confirm that the PROT bit of the UF0IS1 register is 0 before reading data from the UF0E0R register. If the PROT bit is 1, it means that invalid data is retained. Clear the FIFO by FW (the EP0NKR bit is automatically cleared to 0). If the PROT bit of the UF0IS1 register as set. When reading data from the UF0E0R register has been completed (when the counter of the UF0E0R register has been cleared to 0), the hardware automatically clears the EP0NKR bit to 0.

## (2) UF0 EP0NAKALL register (UF0E0NA)

This register controls NAK to all the requests of Endpoint0. It is also valid for automatically executed requests. This register can be read or written in 8-bit units.

#### (3) UF0 EPNAK register (UF0EN)

This register controls NAK of endpoints other than Endpoint0.

This register can be read or written in 8-bit units (however, bits 6 to 4, 1, and 0 can only be read).

The BKO2NK bit can be written only when the BKO2NKM bit of the UF0ENM register is 1 and the BKO1NK bit can be written only when the BKO1NKM bit of the UF0ENM register is 1.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 1 to 4, 7, 8) and the current setting of the interface.

It takes five USB clocks to reflect the status on this register after the UF0FIC0 and UF0FIC1 registers have been set. If it is necessary to read the status correctly, therefore, separate a write signal that accesses the UF0FIC0 and UF0FIC1 registers from a read signal that accesses the UF0EPS0, UF0EPS1, UF0EPS2, UF0E0N, and UF0EN registers by at least four USB clocks.

While NAK is being transmitted to Endpoint0 Read, Endpoint2, and Endpoint4, a write access to the BKO1NK and BKO2NK bits is ignored.

Be sure to clear bit 7 to 0. If it is set to 1, the operation is not guaranteed.

		Data is correctly written to the FIFO connected to the CPU bus side (writing has
		been completed and the FIFO is full or the UF0DEND register is set).
		• The value of the FIFO counter connected to the SIE side is 0.
		This bit is automatically set to 1 and data transmission is started when the FIFO on the

Cautions 1. If DMA is enabled while data is being written to the UF0BI1 register in the PIO mode, a DMA request is immediately issued.

- 2. If 64-byte data is written in the DMA transfer mode, the DMA request signal becomes inactive. If the BKI1NK bit is then set to 1, data is transmitted in synchronization with an IN token. The DMA request signal becomes active again as long as the DMA request is not masked as soon as the FIFO is toggled. If the BKI1NK bit is not set, data is not transmitted even if an IN token has been received. In this case, set the BKI1DED bit of the UF0DEND register to 1.
- 3. If the TC signal is received in the DMA transfer mode, the DMA request signal becomes inactive. At the same time, the DMA request is masked. If the BKI1NK bit is not set to 1, data is not transmitted even if an IN token is received. When the BKI1DED bit of the UF0DEND register is set to 1 by FW, data is transmitted in synchronization with the IN token. To execute DMA transfer again, unmask the DMA request.

## (4) UF0 EPNAK mask register (UF0ENM)

This register controls masking a write access to the UF0EN register. This register can be read or written in 8-bit units (however, bits 6 to 4, 1, and 0 can only be read). Be sure to clear bit 7 to 0. If it is set to 1, the operation is not guaranteed.

#### (6) UF0 CLR request register (UF0CLR)

This register indicates the target of the received CLEAR\_FEATURE request.

This register is read-only, in 8-bit units.

This register is meaningful only when an interrupt request is generated. Each bit is set to 1 after completion of the status stage, and automatically cleared to 0 when this register is read.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 1 to 4, 7, 8) and the current setting of the interface.

#### (8) UF0 EP status 0 register (UF0EPS0)

This register indicates the USB bus status and the presence or absence of register data.

This register is read-only, in 8-bit units.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 1 to 4, 7, 8) and the current setting of the interface.

It takes five USB clocks to reflect the status on this register after the UF0FIC0 and UF0FIC1 registers have been set. If it is necessary to read the status correctly, therefore, separate writing to the UF0FIC0 and UF0FIC1 registers from reading from the UF0EPS0, UF0EPS1, UF0EPS2, UF0E0N, and UF0EN registers by at least four USB clocks.

# (20) UF0 INT mask 4 register (UF0IM4)

This register controls masking of the interrupt sources indicated by the UF0IS4 register.

This register can be read or written in 8-bit units.

FW can mask occurrence of an interrupt request from USBF (INTUSB2B) by writing 1 to the corresponding bit of this register.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 1 to 4, 7, 8) and the current setting of the interface.

#### (26) UF0 INT & DMARQ register (UF0IDR)

This register selects reporting via an interrupt request or starting DMA.

This register can be read or written in 8-bit units.

If data exists in either the UF0BO1 or UF0BO1 register, or if data can be written to the UF0BI1 or UF0BI2 register, this register selects whether it is reported to the FW by an interrupt request, or whether starting DMA is requested. If starting DMA is requested, the DMA transfer mode can be selected according to the setting of bits 0 and 1.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 1 to 4) and the current setting of the interface.

Be sure to clear bits 3 and 2 to 0. If they are set to 1, the operation is not guaranteed.

Caution If the target endpoint is not supported by the SET\_INTERFACE request under DMA transfer, the DMA request signal becomes inactive immediately, and the corresponding bit is automatically cleared to 0 by hardware.

# (30) UF0 FIFO clear 1 register (UF0FIC1)

This register clears each FIFO.

This register is write-only, in 8-bit units. If this register is read, 00H is read.

FW can clear the target FIFO by writing 1 to the corresponding bit of this register. The bit to which 1 has been written is automatically cleared to 0. Writing 0 to the bit is invalid.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 2, 4) and the current setting of the interface.

# (31) UF0 data end register (UF0DEND)

This register reports the end of writing to the transmission system.

This register is write-only, in 8-bit units (however, bits 7 and 6 can be read and written). If this register is read, 00H is read.

FW can start data transfer of the target endpoint by writing 1 to the corresponding bit of this register. The bit to which 1 has been written is automatically cleared to 0. Writing 0 to the bit is invalid.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 1, 3, 7, 8) and the current setting of the interface.

# (32) UF0 GPR register (UF0GPR)

This register controls USBF and the USB interface.

This register can be read or written in 8-bit units (however, bit 0 can only be written). If this register is read, 00H is read.

FW can reset the USBF by writing 1 to bit 0 of this register. This bit is automatically cleared to 0 after 1 has been written to it. Writing 0 to this bit is invalid.

## (33) UF0 mode control register (UF0MODC)

This register controls CPUDEC processing.

This register can be read or written in 8-bit units.

By setting each bit of this register, the setting of the UF0MODS register can be changed. The bit of this register is automatically cleared to 0 only at hardware reset and when the MRST bit of the UF0GRP register has been set to 1.

Even if the bit of this register has automatically been set to 1 by hardware, the setting by FW takes precedence.

Be sure to clear bits 7 and 5 to 2 to 0. If they are set to 1, the operation is not guaranteed.

# Caution This register is provided for debugging purposes. Usually, do not set this register except for verifying the operation or when a special mode is used.

#### (36) UF0 active alternative setting register (UF0AAS)

This register specifies a link between the Interface number and Alternative Setting.

This register can be read or written in 8-bit units.

USBF of the V850E/ME2 can set a five-series Alternative Setting (Alternate Setting 0, 1, 2, 3, and 4 can be defined) and a two-series Alternative Setting (Alternative Setting 0 and 1 can be defined) for one Interface.

For example, when the UF0AIFN register is set to 82H and the UF0AAS register is set to 15H, Interfaces 0, 1, 2, and 3 are valid. Interfaces 0 and 2 support only Alternative Setting 0. Interface 1 supports Alternative Setting 0 and 1, and Interface 3 supports Alternative Setting 0, 1, 2, 3, and 4. With this setting, requests GET\_INTERFACE wIndex = 0/1/2/3, SET\_INTERFACE wValue = 0 & wIndex = 0/2, SET\_INTERFACE wValue = 0/1 & wIndex = 1, and SET\_INTERFACE wValue = 0/1/2/3/4 & wIndex = 3 are automatically responded to, and a STALL response is made to the other GET/SET\_INTERFACE requests.

# (37) UF0 alternative setting status register (UF0ASS)

This register indicates the current status of the Alternative Setting.

This register is read-only, in 8-bit units.

Check this register when the SET\_INT interrupt request has been issued. The value received by the SET\_INTERFACE request is reflected on the UF0IFn register (n = 0 to 4) as well as on this register.

This register can be read or written in 8-bit units.

The setting of this register and the Alternative Setting selected by the SET\_INTERFACE request indicate whether Endpoint8 is currently valid, and the hardware determines how the GET\_STATUS/CLEAR\_FEATURE/SET\_FEATURE Endpoint8 request and the IN transaction to Endpoint8 are responded to, and whether the related bits are valid or invalid.

#### 11.4.2 Data hold registers

# (1) UF0 EP0 read register (UF0E0R)

The UF0E0R register is a 64-byte FIFO that stores the OUT data sent from the host in the data stage of control transfer to/from Endpoint0.

This register is read-only, in 8-bit units. A write access to this register is ignored.

The hardware automatically transfers data to the UF0E0R register when it has received the data from the host. When the data has been correctly received, the E0ODT bit of the UF0IS1 register is set to 1. The UF0E0L register holds the quantity of the received data, and an interrupt request (INTUSB0B) is issued. The UF0E0L register always updates the length of the received data while it is receiving data. If the final transfer is correct reception, the interrupt request is generated. If the received to 0 and the interrupt request is not generated.

The data held by the UF0E0R register must be read by FW up to the value of the amount of data read by the UF0E0L register. Check that all data has been read by using the EP0R bit of the UF0EPS0 register (EP0R = 0 when all data has been read). If the value of the UF0E0L register is 0, the EP0NKR bit of the UF0E0N register is cleared to 0, and the UF0E0R register is ready for reception. The UF0E0R register is cleared when the next SETUP token has been received.

Caution	Read all the data stored.	To discard some data, clear the FIFO.

#### (2) UF0 EP0 length register (UF0E0L)

The UF0E0L register stores the data length held by the UF0E0R register.

This register is read-only, in 8-bit units. A write access to this register is ignored.

The UF0E0L register always updates the length of the received data while it is receiving data. If the final transfer is abnormal reception, the UF0E0L register is cleared to 0 and the interrupt request is not generated. The interrupt request is generated only when the reception is normal, and the FW can read as many data from the UF0E0R register as the value read from the UF0E0L register. The value of the UF0E0L register is decremented each time the UF0E0R register has been read.

#### (3) UF0 EP0 setup register (UF0E0ST)

The UF0E0ST register holds the SETUP data sent from the host.

This register is read-only, in 8-bit units. A write access to this register is ignored.

The UF0E0ST register always writes data when a SETUP transaction has been received. The hardware sets the PROT bit of the UF0IS1 register when it has correctly received the SETUP transaction. It sets the CPUDEC bit of the UF0IS1 register in the case of an FW-processed request. Then an interrupt request (INTUSB0B) is issued. In the case of an FW-processed request, be sure to read the request in 8-byte units. If it is not read in 8-byte units, the subsequent requests cannot be correctly decoded. The read counter of the UF0E0ST register is not cleared even when Bus Reset is received. Always read this counter in 8-byte units regardless of whether Bus Reset is received or not.

Because the UF0E0ST register always enables writing, the hardware overwrites data to this register even if a SETUP transaction is received while the data of the register is being read. Even if the SETUP transaction cannot be correctly received, the CPUDEC interrupt request and Protect interrupt request are not generated, but the previous data is discarded. If a SETUP token of less than 8 bytes is received, however, the received SETUP token is discarded, and the previously received SETUP data is retained. If the SETUP token is received more than once when control transfer is executed once, be sure to check the PROT bit of the UF0IS1 register under the conditions below. If PROT bit = 1, read the UF0E0ST register again because the SETUP transaction has been received more than once.

<1> If a request is decoded by FW and the UF0E0R register is read or the UF0E0W register is written

# (4) UF0 EP0 write register (UF0E0W)

The UF0E0W register is a 64-byte FIFO that stores the IN data (passes it to SIE) sent from the host to Endpoint0 in the data stage.

This register is write-only, in 8-bit units. When this register is read, 00H is read.

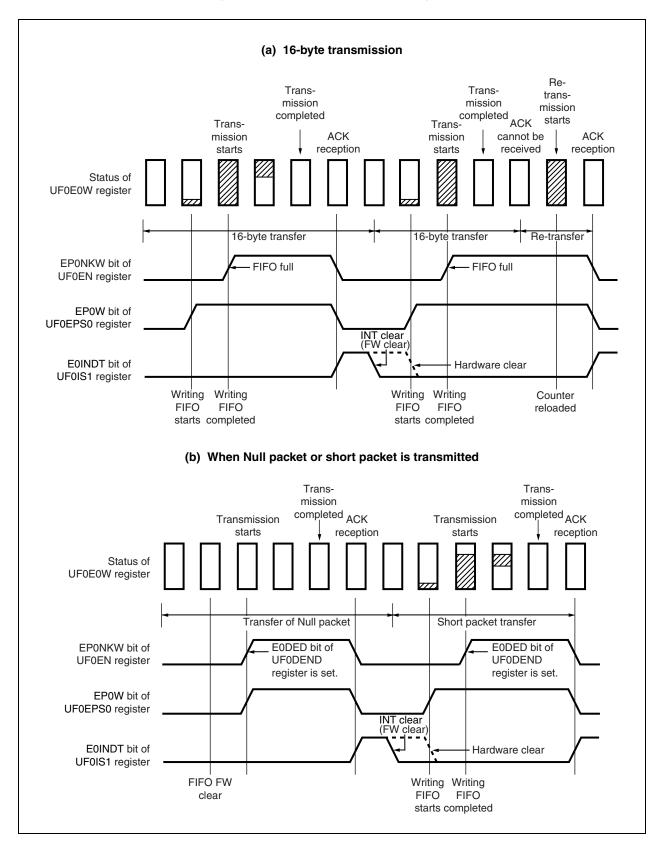

The hardware transmits data to the USB bus in synchronization with an IN token only when the EP0NKW bit of the UF0E0N register is set to 1 (when NAK is not transmitted). When data is transmitted and when the host correctly receives the data, the EP0NKW bit of the UF0E0N register is automatically cleared to 0 by hardware. A short packet is transmitted when data is written to the UF0E0W register and the E0DED bit of the UF0END register is set to 1 (EP0W bit of the UF0EPS0 register = 1 (data exists)). A Null packet is transmitted when the UF0E0W register is cleared and the E0DED bit of the UF0DEND register is set to 1 (EP0W bit of the UF0EDD bit of the UF0DEND register is set to 1 (EP0W bit of the UF0EDD bit of the UF0DEND register is set to 1 (EP0W bit of the UF0EDD bit of the UF0DEND register is set to 1 (EP0W bit of the UF0EDD bit of the UF0DEND register is set to 1 (EP0W bit of the UF0EPS0 register = 1 (data exists)).

The UF0E0W register is cleared to 0 when the next SETUP token is received while transmission has not been completed yet. If the stage of control transfer (read) changes to the status stage while ACK has not been correctly received in the data stage, the UF0E0W register is automatically cleared to 0. At the same time, it is also cleared to 0 if the EP0NKW bit of the UF0E0N register is 1.

If the UF0E0W register is read while no data is in it, 00H is read.

The operation of the UF0E0W register is illustrated below.

# (5) UF0 bulk out 1 register (UF0BO1)

The UF0BO1 register is a 64-byte  $\times$  2 FIFO that stores data for Endpoint2. This register consists of two banks of 64-byte FIFOs each of which performs a toggle operation and repeatedly connects the buses on the SIE and CPU sides. The toggle operation takes place when data is in the FIFO on the SIE side and when no data is in the FIFO on the CPU side (counter value = 0).

This register is read-only, in 8-bit units. A write access to this register is ignored.

When the hardware receives data for Endpoint2 from the host, it automatically transfers the data to the UF0BO1 register. When the register correctly receives the data, a FIFO toggle operation occurs. As a result, the BKO1DT bit of the UF0IS3 register is set to 1, the quantity of the received data is held by the UF0BO1L register, and an interrupt request or DMA request is issued to the CPU. Whether the interrupt request or DMA request is issued to the UF0IDR register.

Read the data held by the UF0BO1 register by FW, up to the value of the amount of data read by the UF0BO1L register. When the correct received data is held by the FIFO connected to the SIE side and the value of the UF0BO1L register reaches 0, the toggle operation of the FIFO occurs, and the BKO1NK bit of the UF0EN register is automatically cleared to 0. If data greater than the value of the UF0BO1L register is read and if the FIFO toggle condition is satisfied, the toggle operation of the FIFO occurs. As a result, the next packet may be read by mistake. Note that, if the toggle condition is not satisfied, the first data is repeatedly read.

If overrun data is received while data is held by the FIFO connected to the CPU side, Endpoint2 stalls, and the FIFO on the CPU side is cleared.

When the UF0BO1 register is read while no data is in it, an undefined value is read.

This register is read-only, in 8-bit units. A write access to this register is ignored.

The UF0BO1L register always updates the received data length while it is receiving data. If the final transfer is abnormal reception, the UF0BO1L register is cleared to 00H, and an interrupt request is not generated. Only if the reception is normal, the interrupt request is generated, and FW can read as much data from the UF0BO1 register as the value read from the UF0BO1L register. The UF0BO2 register is a 64-byte  $\times$  2 FIFO that stores data for Endpoint4. This register consists of two banks of 64-byte FIFOs each of which performs a toggle operation and repeatedly connects the buses on the SIE and CPU sides. The toggle operation takes place when data is in the FIFO on the SIE side and when no data is in the FIFO on the CPU side (counter value = 0).

This register is read-only, in 8-bit units. A write access to this register is ignored.

When the hardware receives data for Endpoint4 from the host, it automatically transfers the data to the UF0BO2 register. When the register correctly receives the data, a FIFO toggle operation occurs. As a result, the BKO2DT bit of the UF0IS3 register is set to 1, the quantity of the received data is held by the UF0BO2L register, and an interrupt request or DMA request is issued to the CPU. Whether the interrupt request or DMA request is issued to the UF0IDR register.

Read the data held by the UF0BO2 register by FW, up to the value of the amount of data read by the UF0BO2L register. When the correct received data is held by the FIFO connected to the SIE side and the value of the UF0BO2L register reaches 0, the toggle operation of the FIFO occurs, and the BKO2NK bit of the UF0EN register is automatically cleared to 0. If data greater than the value of the UF0BO2L register is read and if the FIFO toggle condition is satisfied, the toggle operation of the FIFO occurs. As a result, the next packet may be read by mistake. Note that, if the toggle condition is not satisfied, the first data is repeatedly read.

If overrun data is received while data is held by the FIFO connected to the CPU side, Endpoint4 stalls, and the FIFO on the CPU side is cleared.

### (8) UF0 bulk out 2 length register (UF0BO2L)

The UF0BO2L register stores the length of the data held by the UF0BO2 register.

This register is read-only, in 8-bit units. A write access to this register is ignored.

The UF0BO2L register always updates the received data length while it is receiving data. If the final transfer is abnormal reception, the UF0BO2L register is cleared to 00H, and an interrupt request is not generated. Only if the reception is normal, the interrupt request is generated, and FW can read as much data from the UF0BO2 register as the value read from the UF0BO2L register. ### (9) UF0 bulk in 1 register (UF0BI1)

The UF0BI1 register is a 64-byte  $\times$  2 FIFO that stores data for Endpoint1. This register consists of two banks of 64-byte FIFOs each of which performs a toggle operation and repeatedly connects the buses on the SIE and CPU sides. The toggle operation takes place when no data is in the FIFO on the SIE side (counter value = 0) and when the FIFO on the CPU side is correctly written (FIFO full or BKI1DED bit = 1).

This register is write-only, in 8-bit units. When this register is read, 00H is read.

The hardware transmits data to the USB bus in synchronization with the IN token for Endpoint1 only when the BKI1NK bit of the UF0EN register is set to 1 (when NAK is not transmitted). The address at which data is to be written or read is managed by the hardware. Therefore, FW can transmit data to the host only by writing the data to the UF0BI1 register sequentially. A short packet is transmitted when data is written to the UF0BI1 register and the BKI1DED bit of the UF0DEND register is set to 1 (BKIN1 bit of UF0EPS0 register = 1 (data exists)). A Null packet is transmitted when the UF0BI1 register is cleared and the BKI1DED bit of the UF0EPS0 register = 1 (data exists)). An interrupt request or DMA request can be selected by using the DQBI1MS bit of the UF0IDR register.

The UF0BI2 register is a 64-byte  $\times$  2 FIFO that stores data for Endpoint3. This register consists of two banks of 64-byte FIFOs each of which performs a toggle operation and repeatedly connects the buses on the SIE and CPU sides. The toggle operation takes place when no data is in the FIFO on the SIE side (counter value = 0) and when the FIFO on the CPU side is correctly written (FIFO full or BKI2DED bit = 1).

This register is write-only, in 8-bit units. When this register is read, 00H is read.

The hardware transmits data to the USB bus in synchronization with the IN token for Endpoint3 only when the BKI2NK bit of the UF0EN register is set to 1 (when NAK is not transmitted). The address at which data is to be written or read is managed by the hardware. Therefore, FW can transmit data to the host only by writing the data to the UF0BI2 register sequentially. A short packet is transmitted when data is written to the UF0BI2 register and the BKI2DED bit of the UF0DEND register is set to 1 (BKIN2 bit of UF0EPS0 register = 1 (data exists)). The UF0INT1 register is an 8-byte FIFO that stores data for Endpoint7 (to be passed to SIE).

This register is write-only, in 8-bit units. When this register is read, 00H is read.

The hardware transmits data to the USB bus in synchronization with the IN token for Endpoint7 only when the IT1NK bit of the UF0EN register is set to 1 (when NAK is not transmitted). When the data is transmitted and the host correctly receives it, the IT1NK bit of the UF0EN register is automatically cleared to 0 by hardware. This register stores the value that is to be returned in response to the GET\_STATUS Endpoint0 request. This register can be read or written in 8-bit units. Note, however, that data can be written to this register only when the EP0NKA bit is set to 1.

If an error occurs in USBF, the E0HALT bit is set to 1 by FW. A write access to this register is ignored while a USB-side access to Endpoint0 is being received.

When the E0HALT bit is set to 1 by FW, it is not reflected until the next SETUP token is received if the control transfer immediately before is for the SET\_FEATURE Endpoint0, CLEAR\_FEATURE Endpoint0, GET\_STATUS Endpoint0 request, or an FW-processed request.

The hardware automatically transmits the contents of this register to the host when it has received the GET\_STATUS Endpoint0 request. If Endpoint0 has stalled, the UF0E0W and UF0E0R registers are cleared, and the EP0NKW and EP0NKR bits of the UF0E0N register are cleared to 0.

If an error occurs in Endpoint1, the E1HALT bit is set to 1. A write access to this register is ignored while a USB-side access to Endpoint1 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET\_STATUS Endpoint1 request. If Endpoint1 has stalled, the UF0BI1 register is cleared and the BKI1NK bit is cleared to 0.

Because writing this register is always masked when transfer to Endpoint1, rather than control transfer, is executed, be sure to check this register to see if data has been correctly written to it.

The hardware automatically transmits the contents of this register to the host when it has received the GET\_STATUS Endpoint2 request. If Endpoint2 has stalled, the UF0BO1 register is cleared and the BKO1NK bit is cleared to 0.

Because writing this register is always masked when transfer to Endpoint2, rather than control transfer, is executed, be sure to check this register to see if data has been correctly written to it.

### (5) UF0 EP3 status register L (UF0E3SL)

This register stores the value that is to be returned in response to the GET\_STATUS Endpoint3 request. This register can be read or written in 8-bit units. Note, however, that data can be written to this register only when the EP0NKA bit is set to 1.

If an error occurs in Endpoint3, the E3HALT bit is set to 1. A write access to this register is ignored while a USB-side access to Endpoint3 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET\_STATUS Endpoint3 request. If Endpoint3 has stalled, the UF0BI2 register is cleared and the BKI2NK bit is cleared to 0.

Because writing this register is always masked when transfer to Endpoint3, rather than control transfer, is executed, be sure to check this register to see if data has been correctly written to it.

### (6) UF0 EP4 status register L (UF0E4SL)

This register stores the value that is to be returned in response to the GET\_STATUS Endpoint4 request.

This register can be read or written in 8-bit units. Note, however, that data can be written to this register only when the EP0NKA bit is set to 1.

If an error occurs in Endpoint4, the E4HALT bit is set to 1. A write access to this register is ignored while a USB-side access to Endpoint4 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET\_STATUS Endpoint4 request. If Endpoint4 has stalled, the UF0BO2 register is cleared and the BKO2NK bit is cleared to 0.

Because writing this register is always masked when transfer to Endpoint4, rather than control transfer, is executed, be sure to check this register to see if data has been correctly written to it.

### (7) UF0 EP7 status register L (UF0E7SL)

This register stores the value that is to be returned in response to the GET\_STATUS Endpoint7 request. This register can be read or written in 8-bit units. Note, however, that data can be written to this register only when the EP0NKA bit is set to 1.

If an error occurs in Endpoint7, the E7HALT bit is set to 1. A write access to this register is ignored while a USB-side access to Endpoint7 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET\_STATUS Endpoint7 request. If Endpoint7 has stalled, the UF0INT1 register is cleared and the IT1NK bit is cleared to 0.

Because writing this register is always masked when transfer to Endpoint7, rather than control transfer, is executed, be sure to check this register to see if data has been correctly written to it.

### (8) UF0 EP8 status register L (UF0E8SL)

This register stores the value that is to be returned in response to the GET\_STATUS Endpoint8 request.

This register can be read or written in 8-bit units. Note, however, that data can be written to this register only when the EP0NKA bit is set to 1.

If an error occurs in Endpoint8, the E8HALT bit is set to 1. A write access to this register is ignored while a USB-side access to Endpoint8 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET\_STATUS Endpoint8 request. If Endpoint8 has stalled, the UF0INT2 register is cleared and the IT2NK bit is cleared to 0.

Because writing this register is always masked when transfer to Endpoint8, rather than control transfer, is executed, be sure to check this register to see if data has been correctly written to it.

### (9) UF0 address register (UF0ADRS)

\*

This register stores the device address.

This register is read-only, in 8-bit units.

The device address sent by the SET\_ADDRESS request is analyzed and the resultant value is automatically written to this register. If the SET\_ADDRESS request is processed by FW, the value of this register is reflected as the device address when the SUCCESS signal is received in the status stage.

#### (10) UF0 configuration register (UF0CNF)

This register stores the value that is to be returned in response to the GET\_CONFIGURATION request. This register is read-only, in 8-bit units.

When the SET\_CONFIGURATION request is received, its wValue is automatically written to this register. To change the value of this register by FW after a value other than 00H has been written to the register, write 00H once and then write the desired value. When a change of the value of this register from 00H to other than 00H is detected, the CONF bits are set to 1. If the SET\_CONFIGURATION request is processed by FW, the status of this register is immediately reflected on the UF0MODS register as soon as data has been written to this register (CONF bits = 1 before completion of the status stage).

### (11) UF0 interface 0 register (UF0IF0)

\*

This register stores the value that is to be returned in response to the GET\_INTERFACE wIndex = 0 request. This register is read-only, in 8-bit units.

When the SET\_INTERFACE request is received, its wValue is automatically written to this register.

If the SET\_INTERFACE request is processed by FW, windex and wValue are decoded, and the setting of endpoint is automatically changed. At this time, the status bit of the target endpoint and DPID are automatically cleared to 0, depending on the setting. The FIFO is not cleared automatically.

### (12) UF0 interface 1 to 4 registers (UF0IF1 to UF0IF4)

These registers store the value that is to be returned in response to the GET\_INTERFACE wIndex = n request (n = 1 to 4).

These registers are read-only, in 8-bit units.

When the SET\_INTERFACE request is received, its wValue is automatically written to these registers.

These registers are invalidated according to the setting of the UF0AIFN and UF0AAS registers.

If the SET\_INTERFACE request is processed by FW, windex and wValue are decoded, and the setting of endpoint is automatically changed. At this time, the status bit of the target endpoint and DPID are automatically cleared to 0, depending on the setting. The FIFO is not cleared automatically.

#### (13) UF0 descriptor length register (UF0DSCL)

This register stores the length of the value that is to be returned in response to the GET\_DESCRIPTOR Configuration request. The value of this register is the number of bytes of all the descriptors set by the UF0CIEn register minus 1 (n = 0 to 255). The total descriptor length that is to be returned in response to the GET\_DESCRIPTOR Configuration request is determined according to the value of this register.

This register can be read or written in 8-bit units. However, data can be written to this register only when the EP0NKA bit is set to 1.

Processing of wLength is automatically controlled. If this register is set to 00H, it means that the descriptor to be returned is 1 byte long. If the register is set to FFH, a descriptor length of 256 bytes is returned. When a descriptor exceeding 256 bytes in length is used, set the CDCGDST bit of the UF0MODC register to 1 and process the GET\_DESCRIPTOR request by FW (at this time, the CDCGD bit of the UF0MODS register is also set to 1).

### (14) UF0 device descriptor registers 0 to 17 (UF0DD0 to UF0DD17)

 $\star$ 

These registers store the value to be returned in response to the GET\_DESCRIPTOR Device request. These registers can be read or written in 8-bit units. However, data can be written to these registers only when the EP0NKA bit is set to 1.

- Cautions 1. To rewrite these registers, set the EP0NKA bit to 1 before reading the register contents, and rewrite the register contents after confirming that the bit has been set, in order to prevent conflict between a read access and a write access.
  - 2. Use the value defined by USB Specification Ver. 2.0 and the latest Class Specification as the set value.

### (15) UF0 configuration/interface/endpoint descriptor registers 0 to 255 (UF0CIE0 to UF0CIE255)

These registers store the value to be returned in response to the GET\_DESCRIPTOR Configuration request. These registers can be read or written in 8-bit units. However, data can be written to these registers only when the EP0NKA bit is set to 1.

Descriptor information of up to 256 bytes can be stored in these registers. Store each descriptor in the order of Configuration, Interface, and Endpoint (see **Table 11-5**). If there are two or more Interfaces, repeatedly store the data following the Interface descriptor.

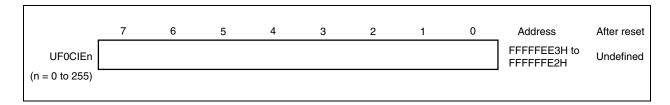

Address	Descriptor Stored
FFFFEE3H	Configuration descriptor (9 bytes)

:	:

Table 11-5. Mapping of UF0CIEn Register

The range of the valid data that can be set to these registers varies according to the setting of the UF0DSCL register. In addition to the descriptors listed in Table 11-6, descriptors peculiar to classes and vendors can also be stored.

If all the values are fixed, they can be stored in ROM.

- Cautions 1. To rewrite these registers, set the EP0NKA bit to 1 before reading the register contents, and rewrite the register contents after confirming that the bit has been set, in order to prevent conflict between a read access and a write access.
  - 2. Use the value defined by USB Specification Ver. 2.0 and the latest Class Specification as the set value.

### 11.4.4 Peripheral control registers

### (1) USB function 0 DMA channel select register (UF0CS)

This register allocates each DMA service of the USB function to a DMA channel.

This register can be read or written in 16-bit units.

To allocate the service of a USB function to a DMA channel by using this register, set this register in advance, set the DTFRn register (n = 0 to 3) of the DMA controller to 7FH, and enable USB\_DMA in advance.

### ★ Caution Setting the same DMA service to different DMA channels and setting different DMA services to the same DMA channel are prohibited.

### 11.5 STALL Handshake or No Handshake

Errors of USBF are defined to be handled as follows.

Transfer Type	Transaction	Target Packet	Error Type	Function Response	Processing
Control transfer/	IN/OUT/SETUP	Token	Endpoint not supported	No response	None
bulk transfer/ interrupt transfer			Endpoint transfer direction mismatch	No response	None
			CRC error	No response	None

Control transfer (data stage)	OUT	Data	Overrun	No response <sup>Note 1</sup>	Set SNDSTL bit of UF0SDS register to 1 and discard received data
Control transfer (status stage)	OUT	Data	Overrun	ACK or no response <sup>Note 2</sup>	Set SNDSTL bit of UF0SDS register to 1 and discard received data
Bulk transfer	OUT	Data	Overrun	No response <sup>Note 1</sup>	Set EnHALT bit of UF0EnSL register (n = 0 to 4, 7, 8) to 1
Control transfer/ bulk transfer/	IN	Handshake	PID check error	-	Hold transferred data and re-transfer data <sup>Note 3</sup>
interrupt transfer			Unsupported PID (other than ACK PID)	_	Hold transferred data and re-transfer data <sup>Note 3</sup>
			Timeout	_	Hold transferred data and re-transfer data <sup>Note 3</sup>

Notes 1. A STALL response is made to re-transfer by the host.

- 2. An ACK response is made if the transfer data is of less than MaxPacketSize and the data received in the status stage is discarded. If MaxPacketSize is exceeded, no response is made, the SNDSTL bit of the UF0SDS register is set to 1, and the received data is discarded.
- **3.** If an OUT transaction indicating a change from the data stage to the status stage is received during control transfer, an error is not handled and it is assumed that reception has been correctly completed.
- Cautions 1. It is judged by the Alternative Setting number currently set whether the target Endpoint is valid or invalid.
  - 2. For the response to the request included in control transfer to/from Endpoint0, see 11.3 Requests.

- **Notes 1.** This register can be cleared to 0 by the RESET signal because its write pointer, counter, and read pointer are cleared to 0 when the RESET signal becomes active, in the same manner as clearing by the UF0FICn register, as the register is controlled by FIFO.
  - 2. This register cannot be cleared to 0. Because data can be written to it by FW, however, any value can be written to the register (before doing so, however, be sure to set the EP0NKA bit of the UF0E0NA register to 1).

## 11.7 FW Processing

The following FW processing is performed.

- Setting processing on device side for the SET\_CONFIGURATION, SET\_INTERFACE, SET\_FEATURE, and CLEAR\_FEATURE requests during enumeration processing
- Analysis and processing of XXXXStandard, XXXXClass, and XXXXVendor requests not subject to automatic processing
- Reading data following bulk-transferred OUT token from receive buffer
- Writing data to be returned in response to bulk-transferred IN token
- Writing data to be returned in response to interrupt-transferred token

The following table lists the requests supported by FW.

 $\star$ 

# Table 11-8. FW-Supported Standard Requests

Request	Reception Side	Processing/ Frequency	Explanation
CLEAR_FEATURE	Interface	Automatic STALL response	It is considered that this request does not come to Interface because there is no function selector value, though it is reserved for bmRequestType. When this request is received, the hardware makes an automatic STALL response.
SET_FEATURE	Interface	Automatic STALL response	It is considered that this request does not come to Interface because there is no function selector value, though it is reserved for bmRequestType. When this request is received, the hardware makes an automatic STALL response.
GET_DESCRIPTOR	String	FW	Returns the string descriptor. When this request is received by the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the request from the CPUDEC interrupt request, and writes the data to be returned to the host, to the UF0E0W register.
SET_DESCRIPTOR	Device	FW	Rewrites the device descriptor. When this request is received by the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the request from the CPUDEC interrupt request, and the writes the data for the next control transfer (OUT) to the UF0DDn register (n = 0 to 17).
SET_DESCRIPTOR	Configuration	FW	Rewrites the configuration descriptor. When this request is received by the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the request from the CPUDEC interrupt request, and the writes the data for the next control transfer (OUT) to the UF0CIEn register (n = 0 to 255).
SET_DESCRIPTOR	String	FW	Rewrites the string descriptor. When this request is received by the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the request from the CPUDEC interrupt request, and loads the data for the next control transfer (OUT).
Other	NA	FW	When this request is received by the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the request from the CPUDEC interrupt request, and performs the necessary processing.

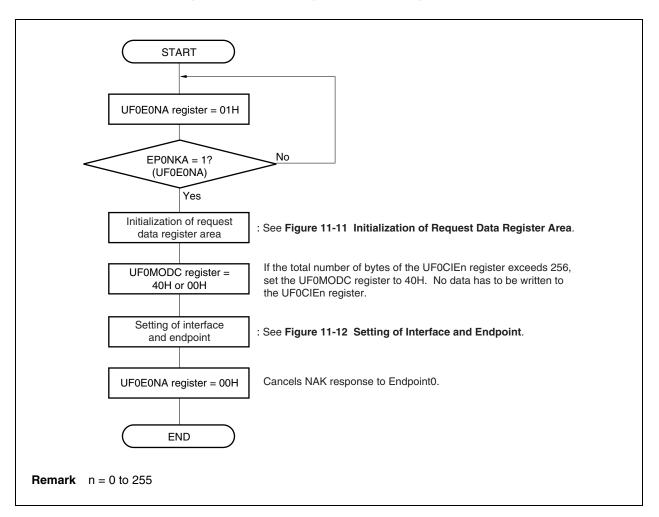

#### 11.7.1 Initialization processing

Initialization processing is executed in the following two ways.

- · Initialization of request data register area
- Setting of interrupt

When the request data register area is initialized, data for the GET\_XXXX request to which a value is to be automatically returned is written and an endpoint is allocated to an interface. In the interrupt settings, the interrupt sources that do not have to be checked can be masked by using the UF0IMn register (n = 0 to 4).

The following flowcharts illustrate the above processing.

#### Figure 11-10. Initializing Request Data Register Area

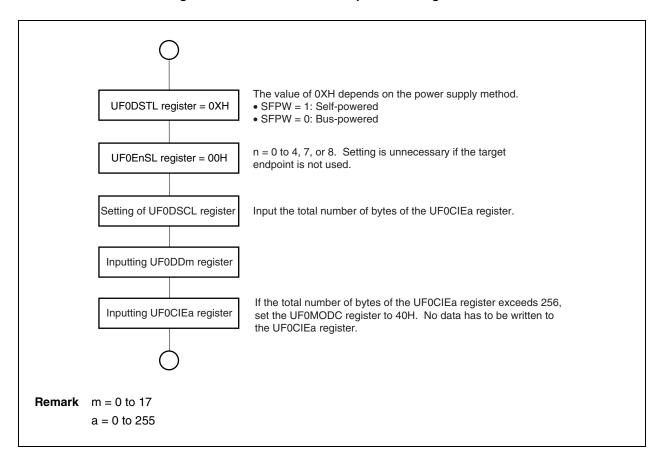

Figure 11-11. Initialization of Request Data Register Area

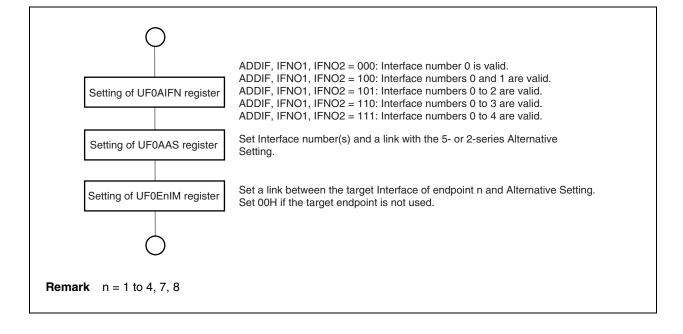

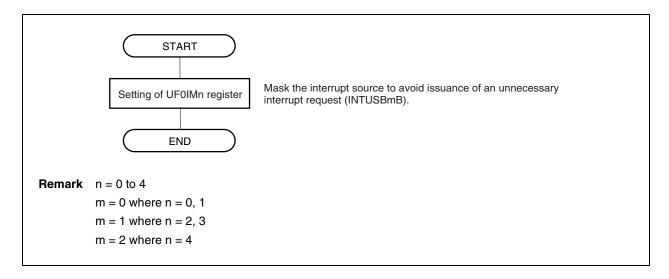

Figure 11-13. Setting of Interrupt

## 11.7.2 Interrupt servicing

The following flowchart illustrates how an interrupt is serviced.

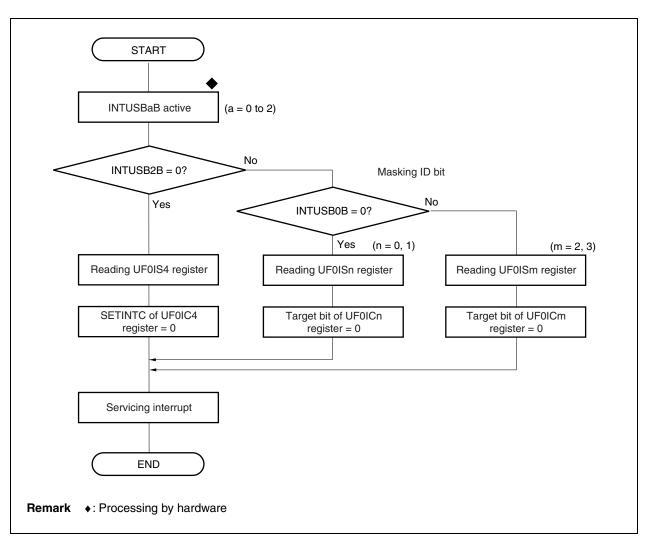

Figure 11-14. Interrupt Servicing

The following bits of the UF0ISn register are automatically cleared by hardware when a given condition is satisfied (n = 1 to 4).

- E0INDT, E0ODT, SUCES, STG, and CPUDEC bits of UF0IS1 register
- BKI2DT, BKI1DT, IT2DT, and IT1DT bits of UF0IS2 register
- BKO2FL, BKO2DT, BKO1FL, and BKO1DT bits of UF0IS3 register

Because clearing an interrupt source by the UF0ICn register is given a lower priority than setting an interrupt source by hardware, the interrupt source may not be cleared depending on the timing (n = 0 to 4).

#### 11.7.3 USB main processing

USB main processing involves processing USB transactions. The types of transactions to be processed are as follows.

- · Fully automatically processed request for control transfer
- Automatically processed requests for control transfer

(SET\_CONFIGURATION, SET\_INTERFACE, SET\_FEATURE, CLEAR\_FEATURE)

- CPUDEC request for control transfer
- Processing for bulk transfer (IN)
- Processing for bulk transfer (OUT)
- Processing for interrupt transfer (IN)

Processing for endpoint n involves writing or reading for data transfer. The flowchart shown below is for PIO.

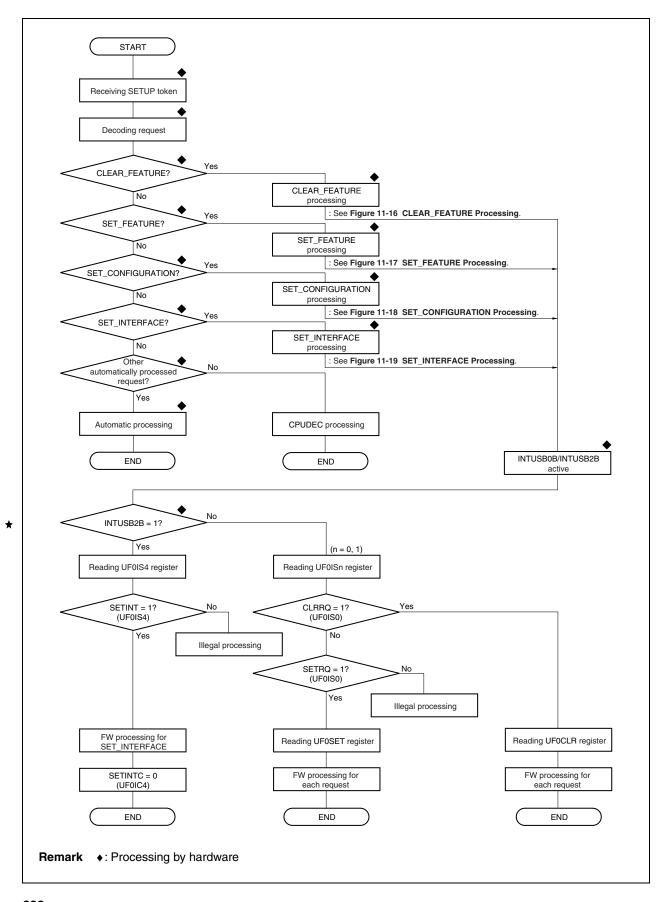

### (1) Fully automatically processed request for control transfer

Because the fully automatically processed request for control transfer is executed by hardware, it cannot be referenced by FW. Therefore, FW does not have to perform any special processing for this request.

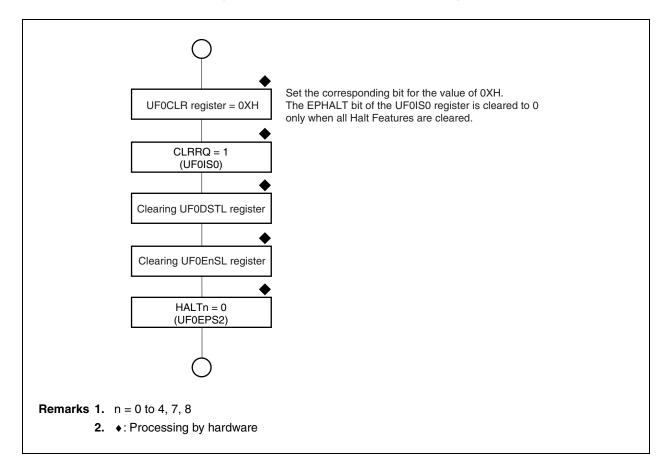

### (2) Automatically processed requests for control transfer

(SET\_CONFIGURATION, SET\_INTERFACE, SET\_FEATURE, CLEAR\_FEATURE) Processing to write a register for automatically processed requests for control transfer, such as SET\_CONFIGURATION, SET\_INTERFACE, SET\_FEATURE, and CLEAR\_FEATURE requests, is automatically executed by hardware, but an interrupt request is issued for recognition on the device side. This processing may be ignored if there is no special processing to be executed.

The flowcharts are shown below.

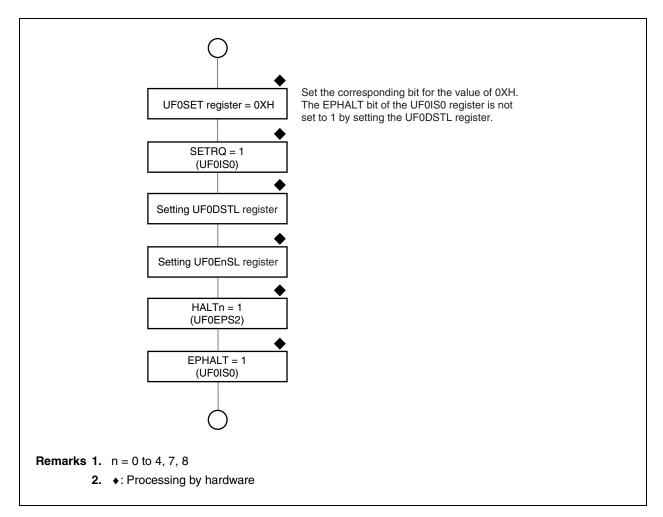

### Figure 11-16. CLEAR\_FEATURE Processing

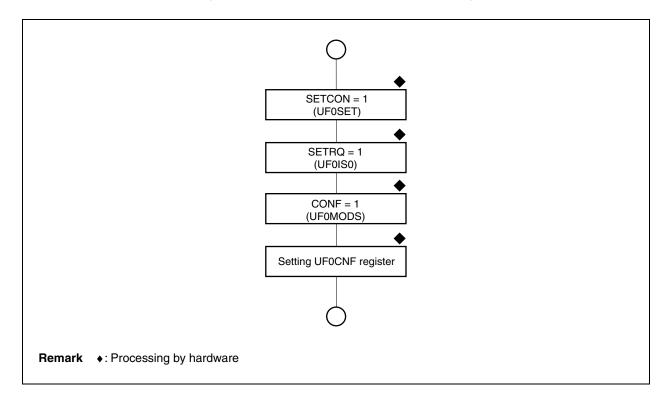

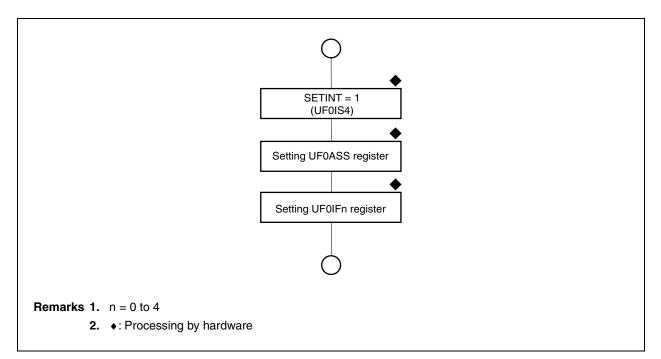

Figure 11-18. SET\_CONFIGURATION Processing

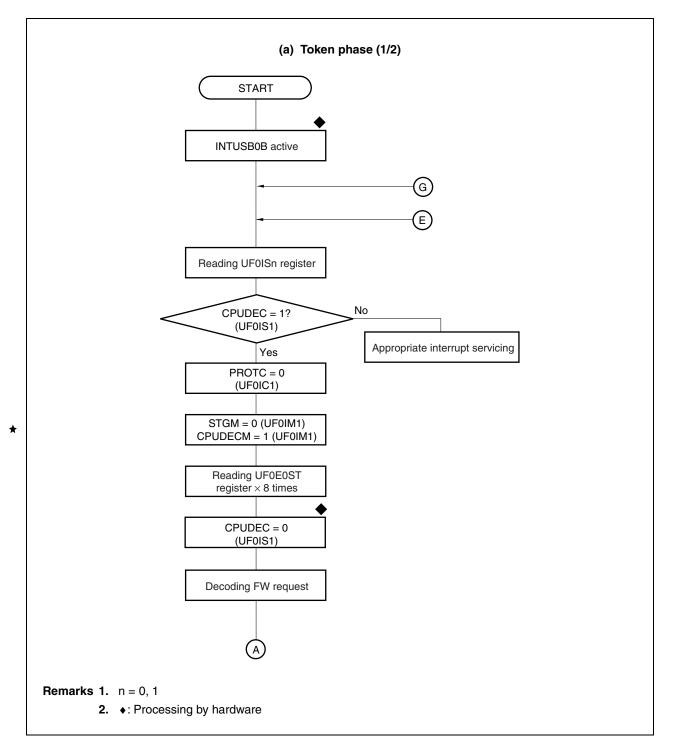

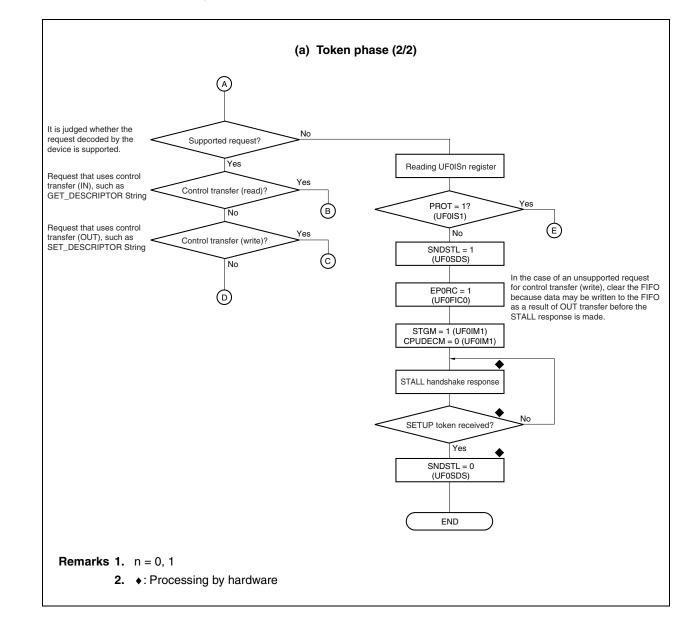

#### (3) CPUDEC request for control transfer

The CPUDEC request can be classified into three types of processing: control transfer (write), control transfer (read), and control transfer (without data). Control transfer (write) indicates a request that uses the OUT transaction in the data stage (e.g., SET\_DESCRIPTOR), and control transfer (read) indicates a request that uses the IN transaction in the data stage (e.g., GET\_DESCRIPTOR). Control transfer (without data) indicates a request that has no data stage (e.g., SET\_CONFIGURATION).

The flowcharts are shown below.

## (4) Processing for bulk transfer (IN)

Bulk transfer (IN) is allocated to Endpoint1 and Endpoint3. The flowchart shown below illustrates how Endpoint1 is controlled. Endpoint3 can also be controlled in the same sequence. To use this flowchart as the control flow of Endpoint3, therefore, read the bit names of Endpoint1 in the flowchart as those of Endpoint3.

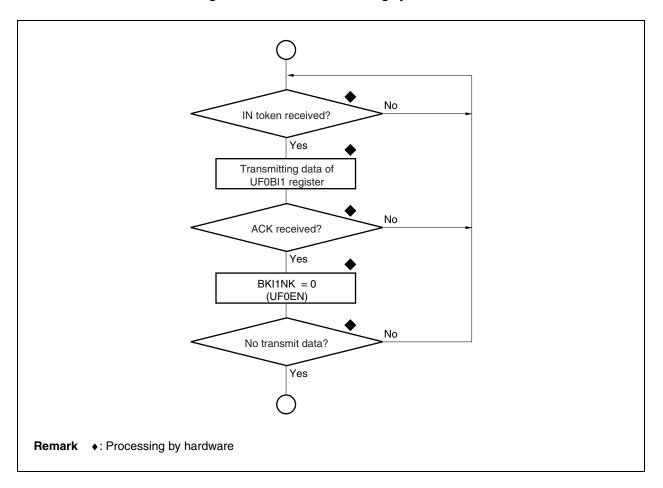

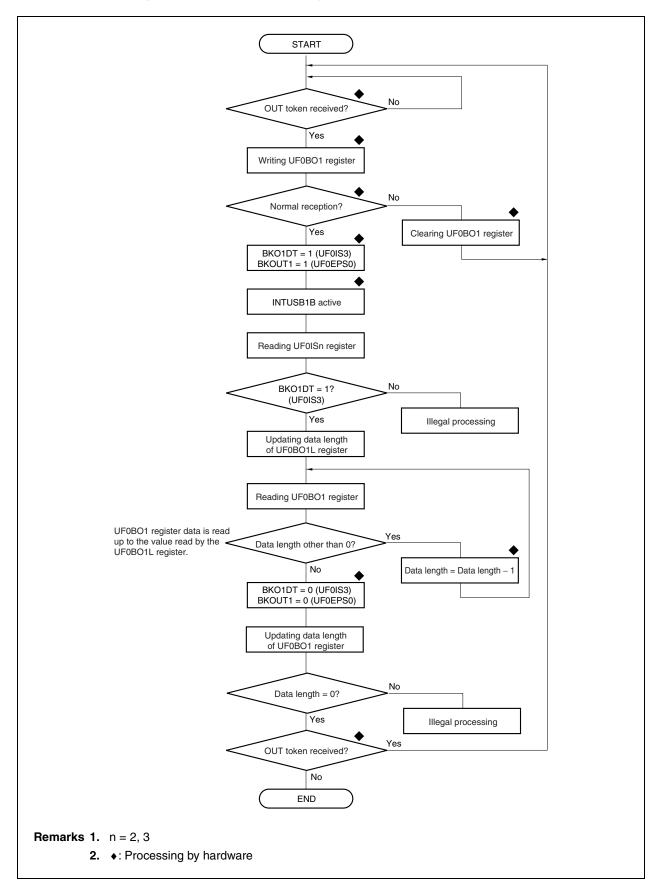

Figure 11-22. Parallel Processing by Hardware

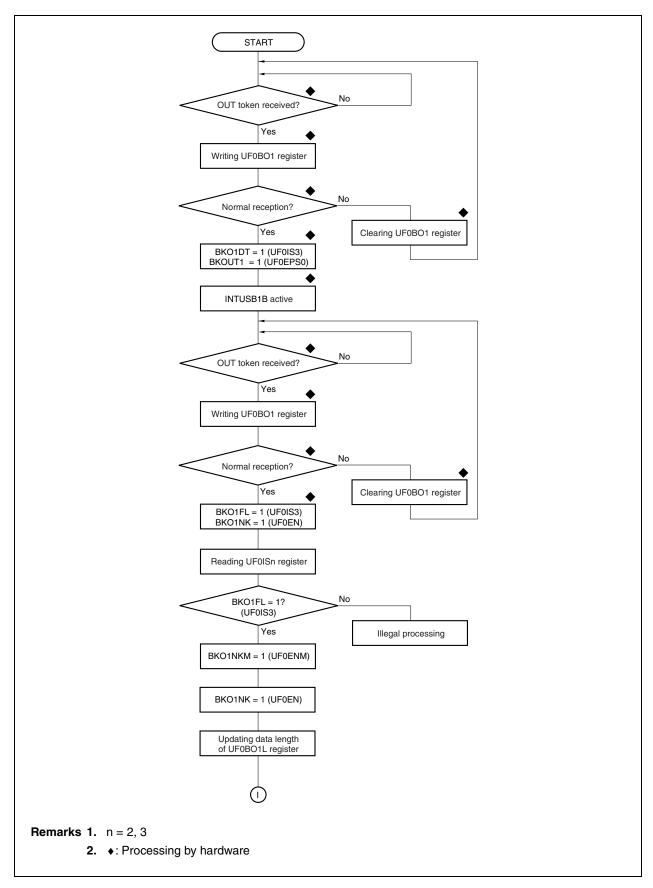

## (5) Processing for bulk transfer (OUT)

Bulk transfer (OUT) is allocated to Endpoint2 and Endpoint4. The flowchart shown below illustrates how Endpoint2 is controlled. Endpoint4 can also be controlled in the same sequence. To use this flowchart as the control flow of Endpoint4, therefore, read the bit names of Endpoint2 in the flowchart as those of Endpoint4.

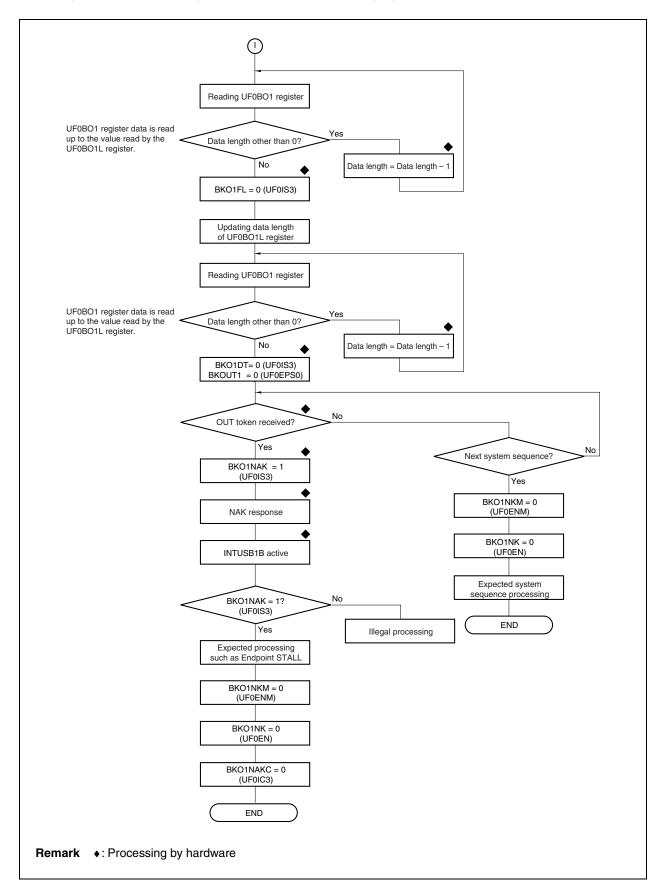

During bulk transfer (OUT), more data may be transmitted from the host than expected by the system. Endpoint2 and Endpoint4 for bulk transfer (OUT) of the V850E/ME2 consist of two 64-byte buffers so that NAK responses are suppressed as much as possible and data can be read from the CPU side even while the bus side is being accessed as the transfer rate of the USB bus increases. Consequently, if the host sends more data than expected by the system, up to 128 bytes of extra data may be automatically received in the worst case. In this case, change the control flow from that of the normal processing of Endpoint2 and Endpoint4 to the flow illustrated below when the quantity of data expected by the system has decreased to two packets. This flowchart illustrates how Endpoint2 is controlled. Endpoint4 can also be controlled in the same sequence. To use this flowchart as the control flow of Endpoint4, therefore, read the bit names of Endpoint2 in the flowchart as those of Endpoint4.

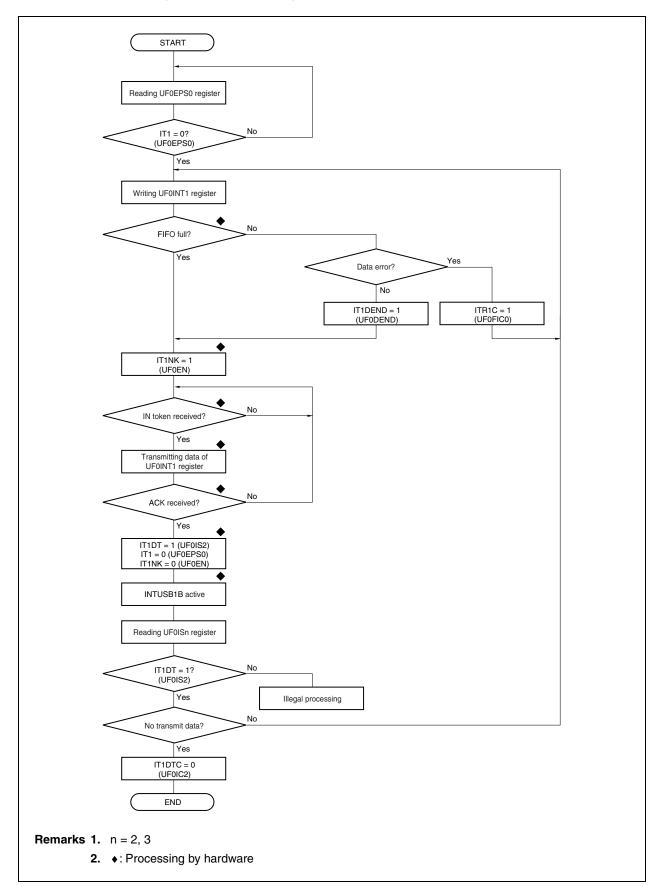

## (6) Processing for interrupt transfer (IN)

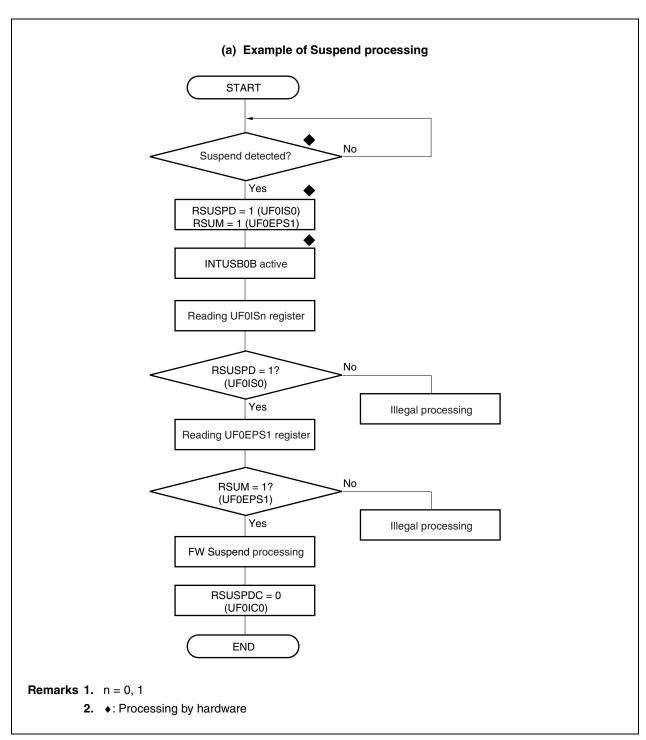

Interrupt transfer (IN) is allocated to Endpoint7 and Endpoint8. The flowchart shown below illustrates how Endpoint7 is controlled. Endpoint8 can also be controlled in the same sequence. To use this flowchart as the control flow of Endpoint8, therefore, read the bit names of Endpoint7 in the flowchart as those of Endpoint8.

#### 11.7.4 Suspend/Resume processing

How Suspend/Resume processing is performed differs depending on the configuration of the system. One example is given below.

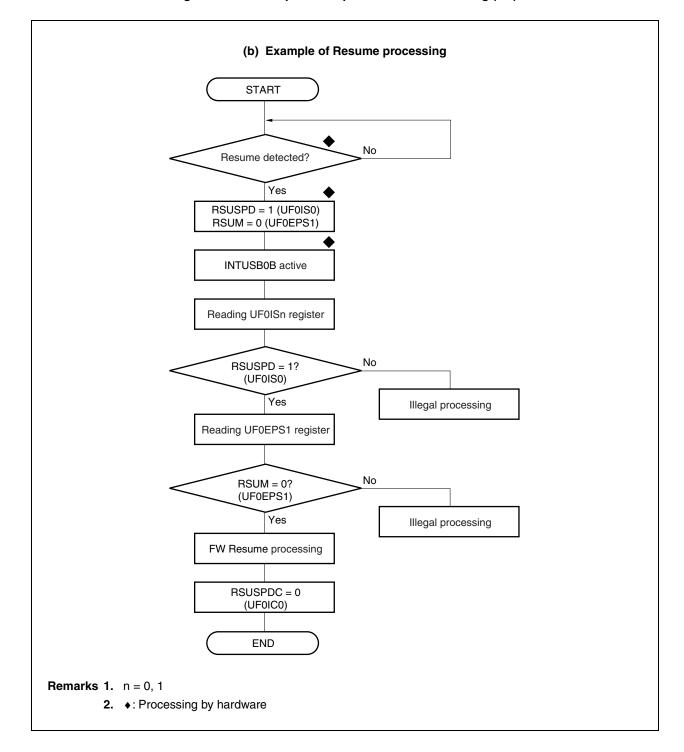

Figure 11-26. Example of Suspend/Resume Processing (2/3)

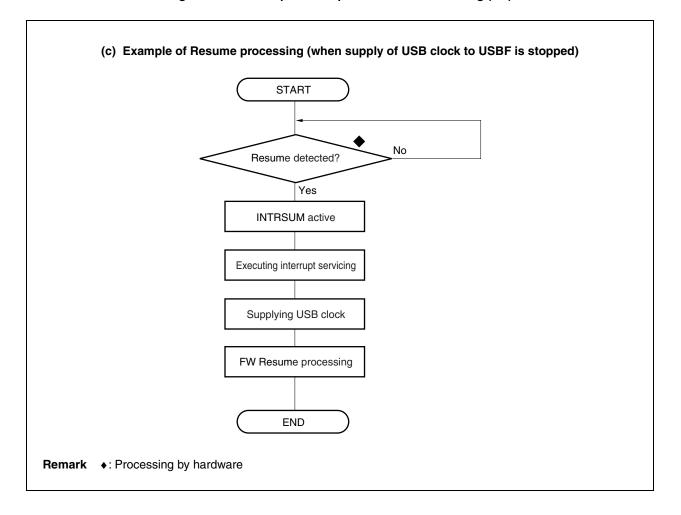

Figure 11-26. Example of Suspend/Resume Processing (3/3)

## 11.7.5 Processing after power application

The processing to be performed after power application differs depending on the configuration of the system. One example is given below.

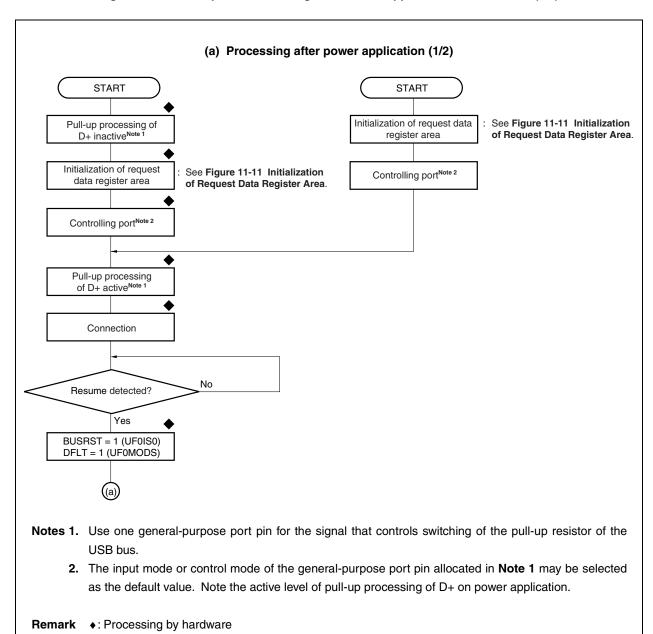

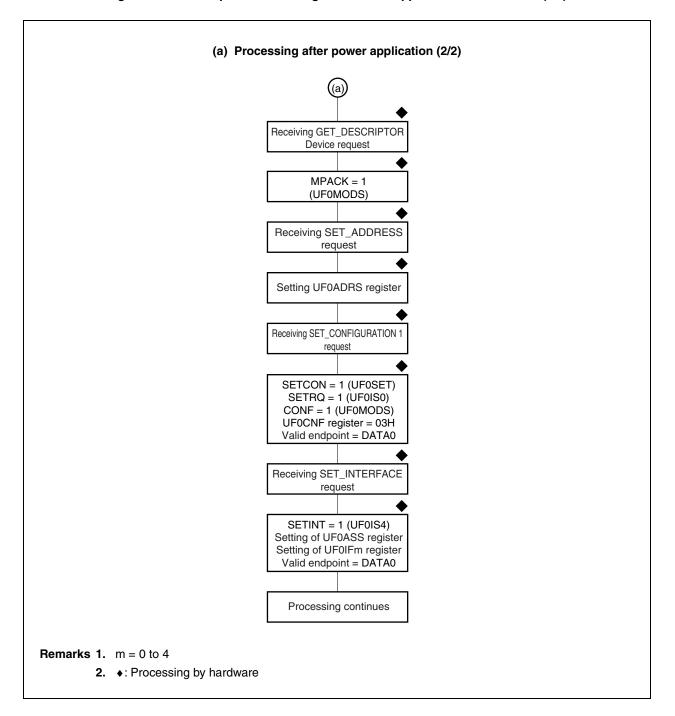

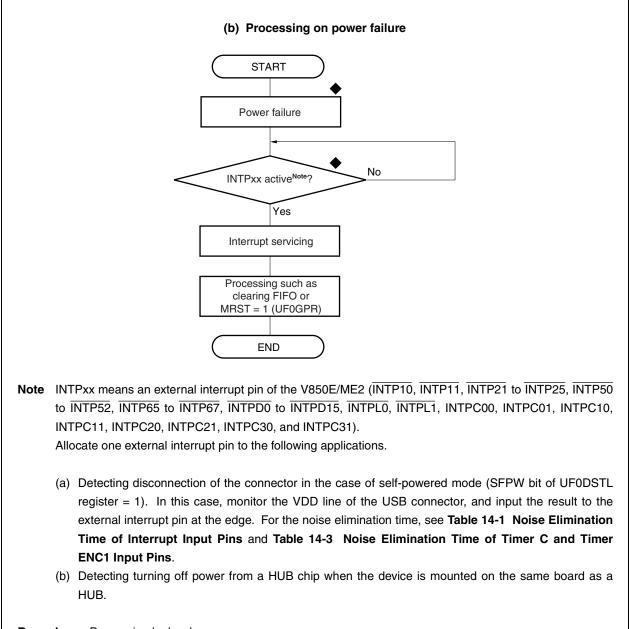

Figure 11-27. Example of Processing After Power Application/Power Failure (1/3)

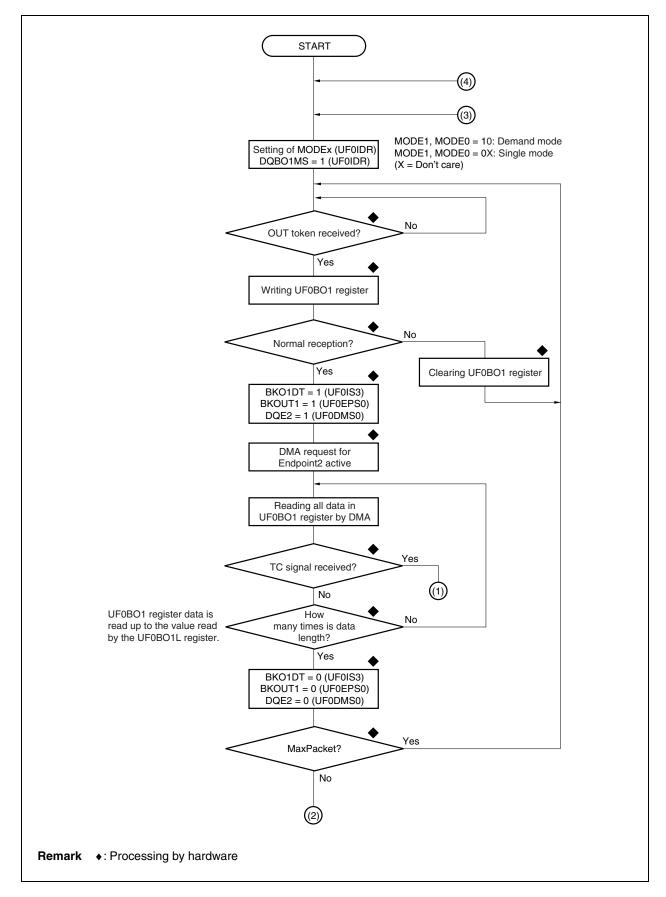

## 11.7.6 Receiving data for bulk transfer (OUT) in DMA mode

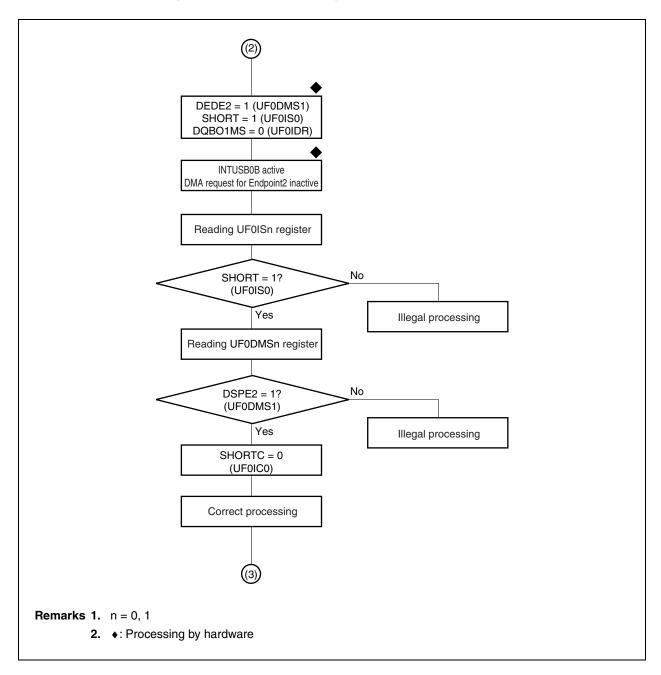

Bulk transfer (OUT) is allocated to Endpoint2 and Endpoint4. The flowchart shown below illustrates how Endpoint2 is controlled when DMA is used. Endpoint4 can also be controlled in the same sequence. To use this flowchart as the control flow of Endpoint4, therefore, read the bit names of Endpoint2 in the flowchart as those of Endpoint4. The control flowchart shown below illustrates how remaining data is read by the CPU.

If data for bulk transfer (OUT) has been correctly received by setting the DQBO1MS bit of the UF0IDR register to 1, the DMA request signal for Endpoint2, instead of an interrupt request (INTUSB1B), becomes active. This DMA request signal for Endpoint2 operates according to the setting of the MODEn bit of the UF0IDR register (n = 0, 1). If all the data stored in the UF0BO1 register has been read by DMA, the DMA request signal for Endpoint2 becomes inactive. In this status, if data for the next bulk transfer (OUT) has been correctly received, the DMA request signal for Endpoint2 becomes active again. If the data for bulk transfer (OUT) that has been received is equal to or less than the FIFO size, a Short interrupt request is issued and the USBSP2B signal becomes active, as soon as reading the data by DMA is completed. As a result, the DQBO1MS bit of the UF0IDR register is cleared to 0, and the DMA request signal for Endpoint2 becomes inactive. To read data by DMA again, set the DQBO1MS bit to 1 again. If DMA is completed by the DMA end signal for Endpoint2, the DQBO1MS bit of the UF0IDR register is cleared to 0, and the DMA request signal for Endpoint2 becomes inactive. At the same time, the DMA\_END interrupt request is issued. If data remains in the UF0BO1 register at this time, DMA can be started again by setting the DQBO1MS bit of the UF0IDR register again. However, the data for bulk transfer (OUT) is always equal to or less than the FIFO size. Consequently, a Short interrupt request is issued, the USBSP2B signal becomes active, the DQBO1MS bit is cleared, and the DMA request signal for Endpoint2 becomes inactive. As soon as the data is read by DMA.

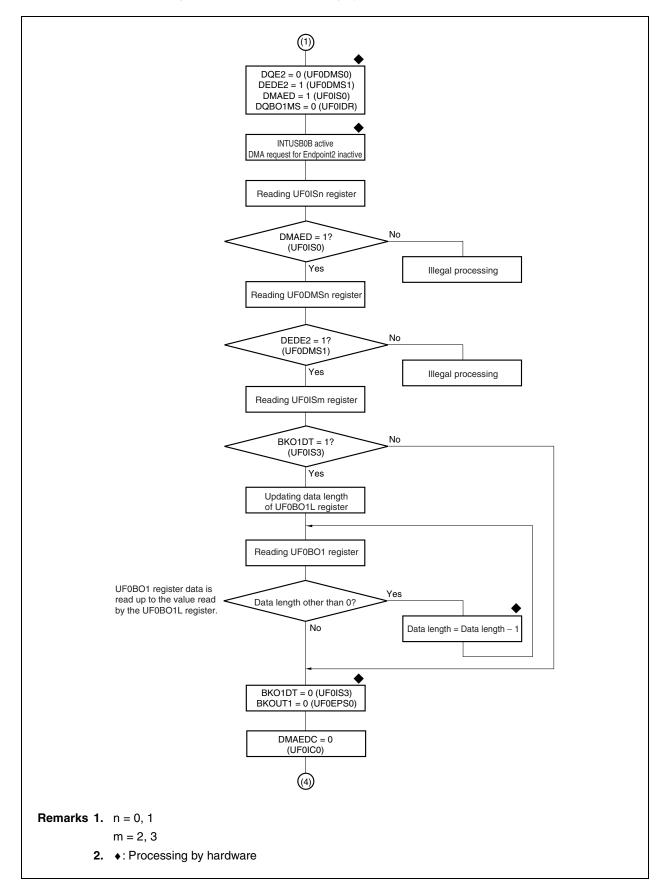

- Cautions 1. The DMA request signal for Endpoint n (n = 2, 4) becomes active in the demand mode (MODE1 and MODE0 bits of the UF0IDR register = 10), as long as there is data to be transferred.
  - 2. The DMA request signal for Endpoint n (n = 2, 4) becomes active in the single mode (MODE1 and MODE0 bits of the UF0IDR register = 0X (X: don't care)) if there is data to be transferred, but this signal becomes inactive each time one byte has been transferred. This operation is repeated until there is no more data to be transferred.

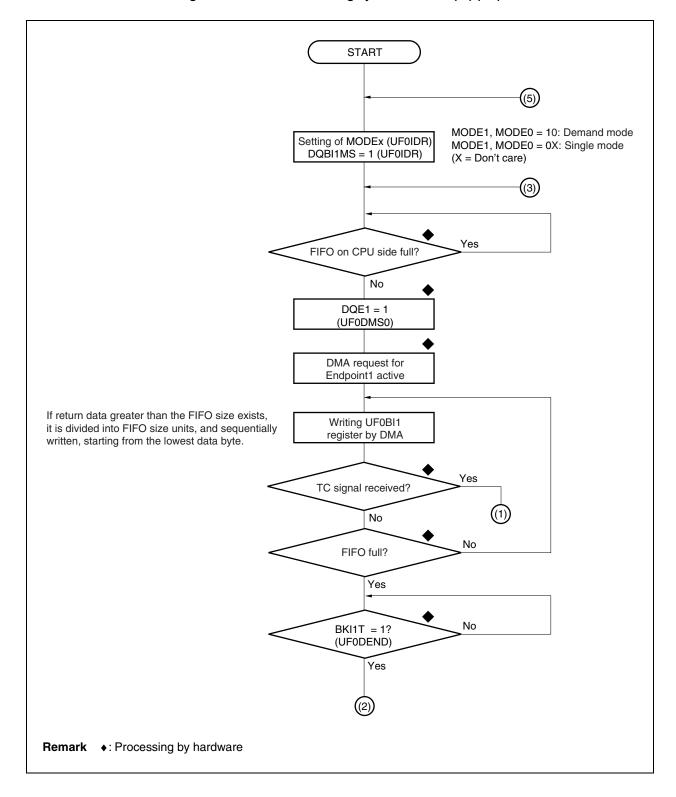

## 11.7.7 Transmitting data for bulk transfer (IN) in DMA mode

Bulk transfer (IN) is allocated to Endpoint1 and Endpoint3. The flowchart shown below illustrates how Endpoint1 is controlled when DMA is used. Endpoint3 can also be controlled in the same sequence. To use this flowchart as the control flow of Endpoint3, therefore, read the bit names of Endpoint1 in the flowchart as those of Endpoint3.

If data for bulk transfer (IN) can be written by setting the DQBI1MS bit of the UF0IDR register to 1, the DMA request signal for Endpoint1, instead of an interrupt request (INTUSB1B), becomes active. This DMA request signal for Endpoint1 operates according to the setting of the MODEn bit of the UF0IDR register (n = 0, 1). If all the data that can be written to the UF0BI1 register has been written by DMA, the DMA request signal for Endpoint1 becomes inactive. In this status, the toggle operation of the FIFO takes place and, if data for bulk transfer (IN) can be written, the DMA request signal for Endpoint1 becomes active again. The automatic toggle operation of the FIFO is not executed even if the FIFO has become full as a result of DMA transfer, unless the BKI1T bit of the UF0DEND register is set to 1. Therefore, be sure to set the BKI1DED bit of the UF0DEND register to 1 to transfer data. If DMA is completed by the DMA end signal for Endpoint1, the DQBI1MS bit of the UF0IDR register is cleared to 0, and the DMA request signal for Endpoint1 becomes inactive. At the same time, the DMA\_END interrupt request is issued. To transmit a short packet at this time when the FIFO is not full, set the BKI1DED bit of the UF0DEND register to 1.

- Cautions 1. The DMA request signal for Endpoint n (n = 1, 3) becomes active in the demand mode (MODE1 and MODE0 bits of the UF0IDR register = 10), as long as data can be transferred.
  - 2. The DMA request signal for Endpoint n (n = 1, 3) becomes active in the single mode (MODE1 and MODE0 bits of the UF0IDR register = 0X (X: don't care)) if data can be transferred, but this signal becomes inactive each time one byte has been transferred. This operation is repeated until there is no more data to be transferred.

#### 11.7.8 USB connection example

\*

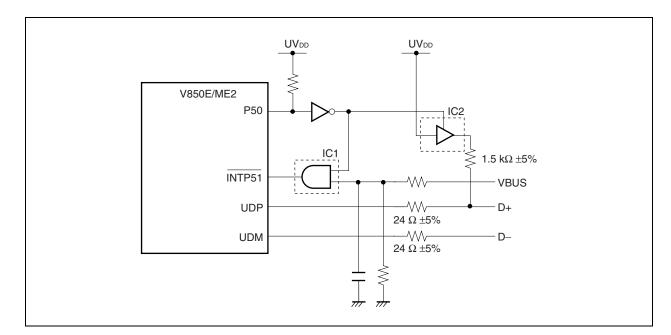

Figure 11-30. USB Connection Example

#### (1) Pull-up control of D+

To prohibit connection report (D+ pull-up) to the USB host/HUB (such as while higher priority processing or initialization processing is under execution), the system must control pulling up of D+ via a general-purpose port. As shown in the circuit example in Figure 11-30, control the pull-up control signal of D+ and VBUS input signal by using a general-purpose port and USB cable VBUS (AND circuit). In Figure 11-30, pulling up D+ is prohibited when the general-purpose port is high level (secure the high level of the general-purpose port pin by pulling it up because the port pin is in the input mode by default). Use an IC to which power can be applied when the system power supply is off as IC2 shown in Figure 11-30.

#### (2) Detecting USB cable connection/disconnection

The USB function controller (USBF) requires a VBUS input signal that recognizes connection and disconnection, because the state of USBF is managed by hardware. Voltage (5 V) is applied from the USB host/HUB as the VBUS input signal if the USB cable VBUS is connected to the USB host/HUB when power to the USBF is turned off. Therefore, use an IC to which power can be applied when the system power supply is off as IC1 shown in Figure 11-30.

# CHAPTER 12 A/D CONVERTER

# 12.1 Features

- 10-bit A/D converter
- On-chip A/D conversion result register (ADCR0 to ADCR7) 10 bits  $\times\,8$
- A/D conversion trigger mode
   A/D trigger mode
   Timer trigger mode

External trigger mode

• Successive approximation method

# 12.2 Configuration

The A/D converter of the V850E/ME2 adopts the successive approximation method, and uses A/D converter mode registers 0, 1, 2 (ADM0, ADM1, ADM2), and the A/D conversion result register (ADCR0 to ADCR7) to perform A/D conversion operations.

## (1) Input circuit

The input circuit selects the analog input (ANI0 to ANI7) according to the mode set by the ADM0, ADM1, and ADM2 registers.

#### (2) C-Array

Holds the charge of the differential voltage between the voltage input from the analog input pins (ANI0 to ANI7) and the reference voltage (1/2 AV<sub>DD</sub>), and redistributes the sampled charges.

#### (3) C-Dummy

This block holds the reference voltage (1/2 AVDD) and assigns the reference of the comparator input.

#### (4) Voltage comparator

The voltage comparator compares the C-Array comparison potential with the C-Dummy reference potential.

#### (5) A/D conversion result register n (ADCRn), A/D conversion result register nH (ADCRnH)

ADCRn is a 10-bit register that holds A/D conversion results. Each time A/D conversion is completed, the conversion results are loaded from the successive approximation register (SAR). RESET input makes this register undefined.

#### (6) ANI0 to ANI7 pins

These are 8-channel analog input pins for the A/D converter. They input the analog signals to be A/D converted.

Caution Make sure that the voltages input to ANI0 to ANI7 do not exceed the rated values. If a voltage higher than AV<sub>DD</sub> or lower than AV<sub>SS</sub> (even within the range of the absolute maximum ratings) is input to a channel, the conversion value of the channel is undefined, and the conversion values of the other channels may also be affected.

## (7) AVREFM and AVREFP pins

This is the pin for inputting the reference voltage of the A/D converter. It converts signals input to the ANI0 to ANI7 pins to digital signals based on the voltage applied between AVREFM and AVREFP.

#### (8) AVss pin

This is the ground pin of the A/D converter. Always use this pin at the same potential as that of the EVss pin even when the A/D converter is not used.

## (9) AVDD pin

This is the analog power supply pin of the A/D converter. Always use this pin at the same potential as that of the EV<sub>DD</sub> pin even when the A/D converter is not used.

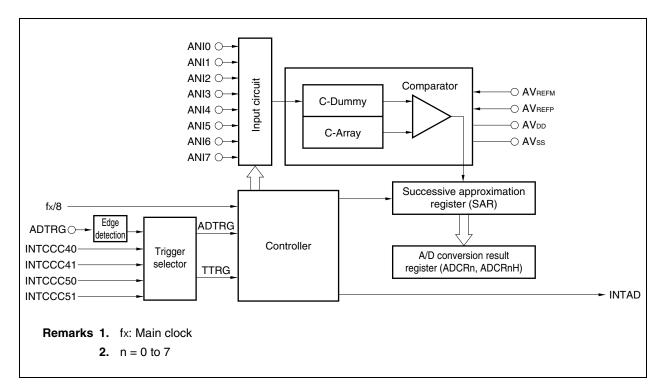

Figure 12-1. Block Diagram of A/D Converter

Cautions 1. If there is noise at the analog input pins (ANI0 to ANI7) or at the reference voltage input pin (AVREFP, AVREFM), that noise may generate an illegal conversion result. Software processing will be needed to avoid a negative effect on the system from this illegal conversion result.

An example of this software processing is shown below.

- Take the average result of a number of A/D conversions and use that as the A/D conversion result.
- Execute a number of A/D conversions consecutively and use those results, omitting any exceptional results that may have been obtained.
- 2. Do not apply a voltage outside the AVREFM to AVREFP range to the pins that are used as A/D converter input pins.

## **12.3 Control Registers**

#### (1) A/D converter mode register 0 (ADM0)

The ADM0 register is an 8-bit register that specifies the operation mode, and executes conversion operations. This register can be read or written in 8-bit or 1-bit units. However, bit 6 can only be read. Writing this bit is ignored.

Cautions 1. When the ADCE bit is 1 in the timer trigger mode and external trigger mode, the trigger signal standby state is set. To clear the ADCE bit, write 0 or reset. In the A/D trigger mode, the conversion trigger is set by writing 1 to the ADCE bit. After the operation, when the mode is changed to the timer trigger mode or external trigger mode without clearing the ADCE bit, the trigger input standby state is set immediately after changing the register.

- Changing the setting of the BS and MS bits is prohibited while A/D conversion is enabled (ADCE bit = 1).
- 3. When data is written to the ADM0 register during an A/D conversion operation, the conversion operation is initialized and conversion is executed from the beginning.

# (2) A/D converter mode register 1 (ADM1)

The ADM1 register is an 8-bit register that specifies the conversion operation time and trigger mode. This register can be read or written in 8-bit or 1-bit units.

- Cautions 1. Changing the setting of the EGA1, EGA0, and FR3 to FR0 bits is prohibited while A/D conversion is enabled (ADCE bit = 1 in the ADM0 register).
  - 2. When data is written to the ADM1 register during an A/D conversion operation, the conversion operation is initialized and conversion is executed from the beginning.

#### Table 12-1. Setting of A/D Conversion Operation Time

Notes 1. Set the conversion operation time in the range of 2 to 10  $\mu$ s (target value).

- 2. After the ADCE bit is set to "1" from "0" to secure the stabilization time of the A/D converter, conversion is started after the A/D stabilization time has elapsed only before the first A/D conversion is executed.
- Cautions 1. Do not change the set value of the A/D conversion time (FR3 to FR0 bits) during an A/D conversion operation (ADCE bit = 1). To change the value, clear the ADCE bit to 0.
  - 2. When the trigger mode (TRG1 and TGR0 bits) is changed midway, A/D conversion can be started immediately without having to secure the A/D stabilization time by re-setting the ADCE bit to "1".

# (3) A/D converter mode register 2 (ADM2)

The ADM2 register is an 8-bit register that specifies the analog input pin of the A/D converter. This register can be read or written in 8-bit or 1-bit units.

- Cautions 1. If a channel for which no analog input pin exists is specified, the result of A/D conversion is undefined.
  - 2. Changing the setting of the ANIS2 to ANIS0 bits is prohibited while A/D conversion is enabled (ADCE bit = 1 in the ADM0 register).
  - 3. When data is written to the ADM2 register during an A/D conversion operation, the conversion operation is initialized and conversion is executed from the beginning.

# (4) ADC trigger select register (ADTS)

This is an 8-bit register that specifies the timer trigger signal in the timer trigger mode. This register can be read or written in 8-bit units.

Be sure to clear bits 7 to 4 to 0. If they are set to 1, the operation is not guaranteed.

# Caution Before changing the setting of the ADTS register, stop the A/D conversion operation (by clearing the ADCE bit of the ADM0 register to 0). The operation is not guaranteed if the setting of the ADTS register is changed while A/D conversion is enabled (ADCE bit = 1).

# (5) A/D conversion result registers 0 to 7, 0H to 7H (ADCR0 to ADCR7, ADCR0H to ADCR7H)

The ADCRn register is a 10-bit register holding the A/D conversion results. There are eight 10-bit registers. These registers are read-only in 16-bit or 8-bit units. During 16-bit access, the ADCRn register is specified, and during higher 8-bit access, the ADCRnH register is specified (n = 0 to 7). When reading the 10-bit data of the A/D conversion results from the ADCRn register, only the higher 10 bits

are valid and the lower 6 bits are always read as 0.

The correspondence between each analog input pin and the ADCRn register is shown below.

The relationship between the analog voltage input to the analog input pins (ANI0 to ANI7) and the A/D conversion result (of the A/D conversion result register (ADCRn)) is as follows:

$$ADCR = INT (\frac{V_{IN}}{AV_{REF}} \times 1,024 + 0.5)$$

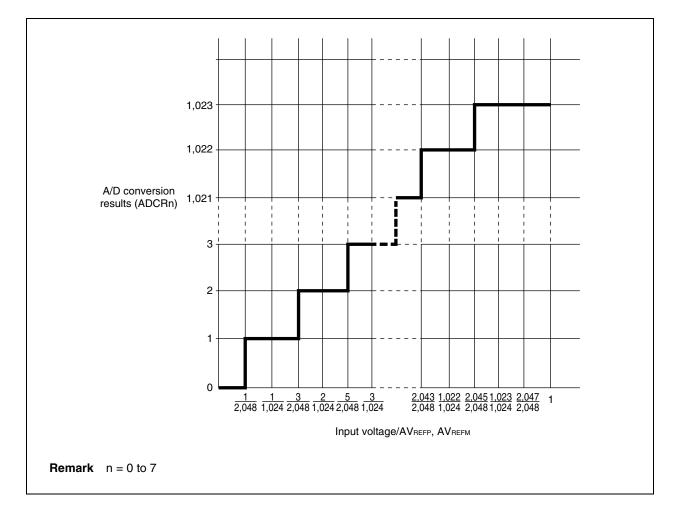

or,

$$(ADCR - 0.5) \times \frac{AV_{REF}}{1,024} \le V_{IN} < (ADCR + 0.5) \times \frac{AV_{REF}}{1,024}$$

INT(): Function that returns the integer of the value in ()
 V<sub>IN</sub>: Analog input voltage
 AV<sub>REF</sub>: AV<sub>REFM</sub>, AV<sub>REFP</sub> pin voltage
 ADCR: Value of A/D conversion result register (ADCRn)

Figure 12-2 shows the relationship between the analog input voltage and the A/D conversion results.

# 12.4 Operation

# 12.4.1 Basic operation

A/D conversion is executed by the following procedure.

- The selection of the analog input and specification of the operation mode, trigger mode, etc. should be specified using the ADMn register<sup>Note 1</sup> (n = 0 to 2).
   When the ADCE bit of the ADM0 register is set to 1, A/D conversion starts in the A/D trigger mode. In the timer trigger mode and external trigger mode, the trigger standby state<sup>Note 2</sup> is set.
- (2) When A/D conversion is started, the C array voltage on the analog input side and the C array voltage on the reference side are compared by the comparator.
- (3) When the comparison of the 10 bits ends, the conversion results are stored in the ADCRn register. When A/D conversion has been performed the specified number of times, the A/D conversion end interrupt (INTAD) is generated (n = 0 to 7).
  - **Notes 1.** If the setting of the ADMn register (n = 0 to 2) is changed during A/D conversion, the operation immediately before is stopped, and the result of the conversion is not stored in the ADCRn register (n = 0 to 7). The A/D conversion operation is then initialized, and conversion is executed from the beginning again.
    - During the timer trigger mode and external trigger mode, if the ADCE bit of the ADM0 register is set to 1, the mode changes to the trigger standby state. The A/D conversion operation is started by the trigger signal (ADCS bit = 1 in the ADM0 register), and the trigger standby state (ADCS bit = 0) is returned when the A/D conversion operation ends.

#### 12.4.2 Operation mode and trigger mode

Various conversion operations can be specified for the A/D converter by specifying the operation mode and trigger mode. The operation mode and trigger mode are set by the ADM0 to ADM2 registers.

The following shows the relationship between the operation mode and trigger mode.

Trigger Mode	Operati	on Mode		Set Value		Analog Input
			ADM0	ADM1	ADM2	
A/D trigger	Select	1 buffer	xx010000B	00000xxxB	00000xxxB	ANI0 to ANI7
		4 buffers	xx110000B		00000xxxB	ANI0 to ANI7

		4 buffers	xx110000B		00000xxxB	ANI0 to ANI7
	Scan		xxx00000B		00000xxxB	ANI0 to ANI7

Table 12-2. Relationship Between Operation Mode and Trigger Mode

#### (1) Trigger mode

There are three types of trigger modes that serve as the start timing of A/D conversion processing: A/D trigger mode, timer trigger mode, and external trigger mode. These trigger modes are set by the TRG1 and TRG0 bits of the ADM1 register.

#### (a) A/D trigger mode

This mode starts the conversion timing of the analog input set to the ANI0 to ANI7 pins, and by setting the ADCE bit of the ADM0 register to 1, starts A/D conversion. Unless the ADCE bit is cleared to 0 after conversion, the next conversion operation is repeated. If data is written to the ADM0 to ADM2 registers during conversion, conversion is stopped and then executed from the beginning again.

#### (b) Timer trigger mode

This mode specifies the conversion timing of the analog input set for the ANI0 to ANI7 pins using the values set to the timer C capture/compare register.

This register creates the analog input conversion timing by generating the compare match interrupts of the four capture/compare registers (CCC40, CCC41, CCC50, CCC51) connected to the 16-bit timer C (TMC4, TMC5).

If the ADCE bit of the ADM0 register is set to 1, the A/D converter waits for an interrupt (INTCCC40, INTCCC41, INTCCC50, or INTCCC51), and starts conversion when INTCCC40, INTCCC41, INTCCC50, or INTCCC51 occurs (ADCS bit = 1 in the ADM0 register). When conversion has finished, the converter waits for an interrupt again (ADCS = 0). If data is written to the ADM0 to ADM2 registers during conversion, conversion is stopped and then executed from the beginning again.

#### (c) External trigger mode

This mode specifies the conversion timing of the analog input to the ANI0 to ANI7 pins using the ADTRG pin.

The EGA1 and EGA0 bits of the ADM1 register are used to specify the valid edge to be input to the ADTRG pin.

When the ADCE bit of the ADM0 register is set to 1, the A/D converter waits for an external trigger (ADTRG), and starts conversion when the valid edge of ADTRG is detected (ADCS bit = 1 in the ADM0 register). When the converter has completed its conversion operation, it waits for an external trigger again (ADCS bit = 0).

If the valid edge is detected at the ADTRG pin during conversion, conversion is executed from the beginning again.

If data is written to the ADM0 to ADM2 registers during conversion, conversion is stopped and then executed from the beginning again.

#### (2) Operation mode

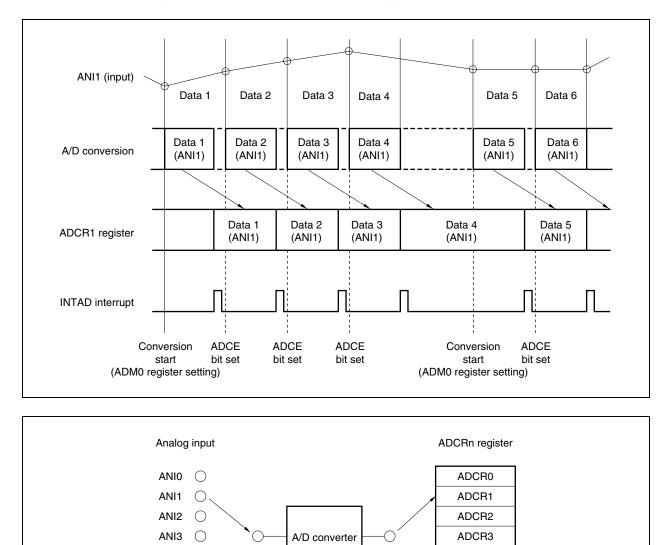

There are two operation modes that set the ANI0 to ANI7 pins: select mode and scan mode. The select mode has sub-modes that consist of 1-buffer mode and 4-buffer mode. These modes are set by the BS and MS bits of the ADM0 register.

#### (a) Select mode

In this mode, one analog input specified by the ADM2 register is A/D converted. The conversion results are stored in the ADCRn register corresponding to the analog input (ANIn). For this mode, the 1-buffer mode and 4-buffer mode are provided for storing the A/D conversion results (n = 0 to 7).

#### • 1-buffer mode

In this mode, one analog input specified by the ADM2 register is A/D converted. The conversion results are stored in the ADCRn register corresponding to the analog input (ANIn) (n = 0 to 7). The ANIn and ADCRn register correspond one to one, and an A/D conversion end interrupt (INTAD) is generated each time one A/D conversion ends. After conversion has finished, the next conversion operation is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

## • 4-buffer mode

In this mode, one analog input is A/D converted four times and the results are stored in the ADCRn register. The A/D conversion end interrupt (INTAD) is generated when the four A/D conversions end (n = 0 to 3 when the lower analog input channel is specified and n = 4 to 7 when the higher analog input channel is specified).

After conversion has finished, the next conversion operation is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

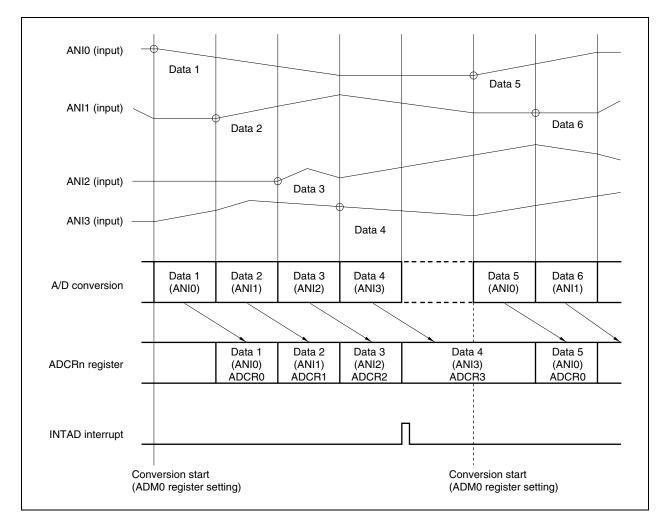

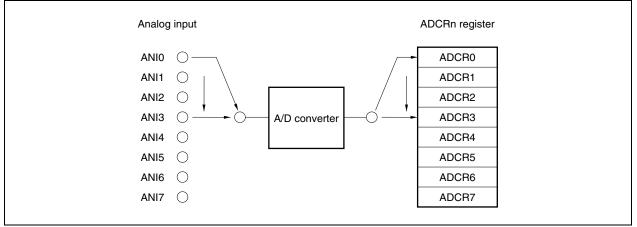

# (b) Scan mode

In this mode, the analog inputs specified by the ADM2 register are selected sequentially from the ANI0 pin, and A/D conversion is executed. The A/D conversion results are stored in the ADCRn register corresponding to the analog input (n = 0 to 7). When the conversion of the specified analog input ends, the A/D conversion end interrupt (INTAD) is generated. After conversion has finished, the next conversion operation is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

# 12.5 Operation in A/D Trigger Mode

When the ADCE bit of the ADM0 register is set to 1, A/D conversion is started.

## 12.5.1 Select mode operation

In this mode, the analog input specified by the ADM2 register is A/D converted. The conversion results are stored in the ADCRn register corresponding to the analog input. In the select mode, the 1-buffer mode and 4-buffer mode are supported according to the storing method of the A/D conversion results (n = 0 to 7).

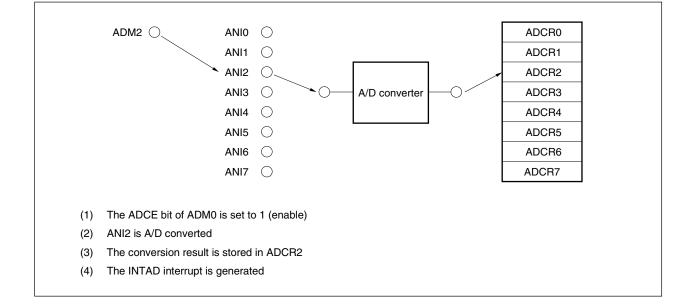

# (1) 1-buffer mode (A/D trigger select: 1 buffer)

In this mode, one analog input is A/D converted once. The conversion results are stored in one ADCRn register. The analog input and ADCRn register correspond one to one.

Each time an A/D conversion is executed, an A/D conversion end interrupt (INTAD) is generated and A/D conversion ends. The next conversion operation is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

Analog Input	A/D Conversion Result Register
ANIn	ADCRn

This mode is most appropriate for applications in which the results of each first-time A/D conversion are read.

#### Figure 12-6. Example of 1-Buffer Mode Operation (A/D Trigger Select: 1 Buffer)

# (2) 4-buffer mode (A/D trigger select: 4 buffers)

In this mode, one analog input is A/D converted four times and the results are stored in the ADCRn register. When the 4th A/D conversion ends, an A/D conversion end interrupt (INTAD) is generated and the A/D conversion is stopped. The next conversion operation is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

	ADCR3 (4th time)
ANI4 to ANI7	ADCR4 (1st time)
	ADCR5 (2nd time)
	ADCR6 (3rd time)
	ADCR7 (4th time)

This mode is suitable for applications in which the average of the A/D conversion results is calculated.

#### 12.5.2 Scan mode operations

In this mode, the analog inputs specified by the ADM2 register are selected sequentially from the ANI0 pin, and A/D conversion is executed. The A/D conversion results are stored in the ADCRn register corresponding to the analog input (n = 0 to 7).

When conversion of all the specified analog input ends, the A/D conversion end interrupt (INTAD) is generated, and A/D conversion is stopped. The next conversion operation is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

This mode is most appropriate for applications in which multiple analog inputs are constantly monitored.

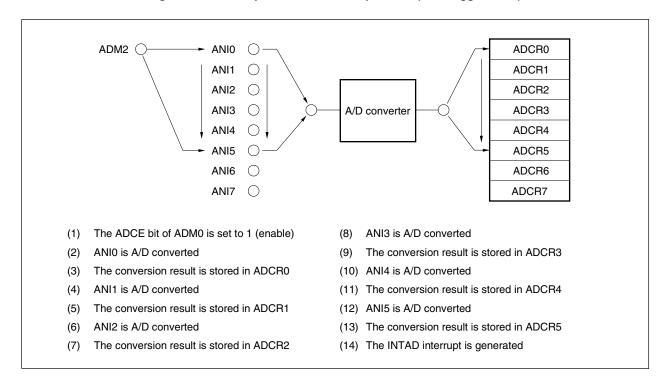

Figure 12-8. Example of Scan Mode Operation (A/D Trigger Scan)

## 12.6 Operation in Timer Trigger Mode

In this mode, the conversion timing of the analog input signal set by the ANI0 to ANI7 pins is defined by the value set to the capture/compare registers of timers C4 and C5.

The analog input conversion timing is generated when a compare match interrupt (INTCCC40, INTCCC41, INTCCC50, or INTCCC51) is generated by the capture/compare register connected to 16-bit timer C4 or C5 (TMC4 or TMC5).

When the ADCE bit of the ADM0 register is set to 1, the A/D converter waits for the interrupt (INTCCC40, INTCCC41, INTCCC50, or INTCCC51), and starts conversion when INTCCC40, INTCCC41, INTCCC50, or INTCCC51 occurs (ADCS bit = 1 in the ADM0 register). When conversion is finished, the converter waits for an interrupt again (ADCS bit = 0).

If INTCCC40, INTCCC41, INTCCC50, or INTCCC51 occurs during conversion, the conversion operation is executed from the beginning again.

If data is written to the ADM0 to ADM2 registers during conversion, the conversion operation is stopped and executed from the beginning again.

## 12.6.1 Select mode operation

In this mode, an analog input (ANI0 to ANI7) specified by the ADM2 register is A/D converted. The conversion results are stored in the ADCRn register corresponding to the analog input. In the select mode, the 1-buffer mode and 4-buffer mode are provided according to the storing method of the A/D conversion results.

## (1) 1-buffer mode (timer trigger select: 1 buffer)

In this mode, one analog input is A/D converted once and the conversion results are stored in one ADCRn register.

One analog input is A/D converted once using the trigger of the match interrupt signals (INTCCC40, INTCCC41, INTCCC50, INTCCC51) and the results are stored in one ADCRn register. An A/D conversion end interrupt (INTAD) is generated for each A/D conversion.

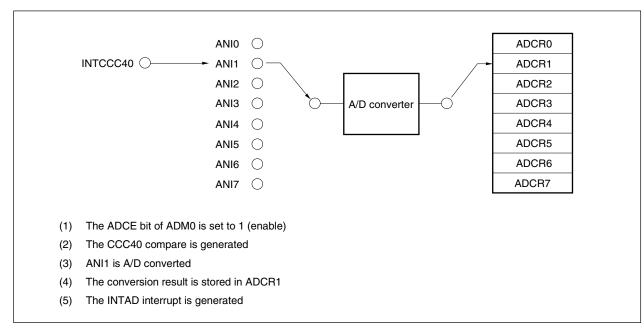

Unless the ADCE bit of the ADM0 register is cleared to 0, A/D conversion is repeated each time a timer match interrupt is generated.

# (2) 4-buffer mode (timer trigger select: 4 buffers)

In this mode, A/D conversion of one analog input is executed four times, and the results are stored in the ADCRn register.

One analog input is A/D converted four times using the match interrupt signals (INTCCC40, INTCCC41, INTCCC50, INTCCC51) as a trigger, and the results are stored in four ADCRn registers. The A/D conversion end interrupt (INTAD) is generated when the four A/D conversions end.

After conversion has finished, the next conversion is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

This mode is suitable for applications in which the average of the A/D conversion results is calculated.

#### 12.6.2 Scan mode operation

In this mode, the analog inputs specified by the ADM2 register are selected sequentially from the ANI0 pin and are A/D converted the specified number of times using the timer match interrupt signal as a trigger.

The result of conversion is stored in the ADCRn register corresponding to the analog input. When all the specified analog input signals have been converted, an A/D conversion end interrupt (INTAD) occurs.

After conversion has finished, the A/D converter waits for a trigger unless the ADCE bit of the ADM0 register is cleared to 0. When a timer match interrupt occurs again, the converter starts A/D conversion again, starting from the ANI0 input.

This mode is most appropriate for applications in which multiple analog inputs are constantly monitored.

# 12.7 Operation in External Trigger Mode

In this mode, the conversion timing of the analog signals input to the ANI0 to ANI7 pins is specified by the ADTRG pin.

Detection of the valid edge at the ADTRG input pin is specified by using the EGA1 and EGA0 bits of the ADM1 register.

When the ADCE bit of the ADM0 register is set to 1, the A/D converter waits for an external trigger (ADTRG), and starts conversion when the valid edge of ADTRG is detected (ADCS bit = 1 in the ADM0 register). When the converter has ended conversion, it waits for the external trigger again (ADCS bit = 0).

If the valid edge is detected at the ADTRG pin during conversion, conversion is executed from the beginning again.

If data is written to the ADM0 to ADM2 registers during conversion, conversion is stopped and executed from the beginning again.

#### 12.7.1 Select mode operations

In this mode, one analog input (ANI0 to ANI7) specified by the ADM2 register is A/D converted. The conversion results are stored in the ADCRn register corresponding to the analog input. In the select mode, there are two select modes: 1-buffer mode and 4-buffer mode, according to the storing method of the conversion results.

#### (1) 1-buffer mode (external trigger select: 1-buffer)

In this mode, one analog input is A/D converted using the ADTRG signal as a trigger. The conversion results are stored in one ADCRn register. The analog input and the A/D conversion results register correspond one to one. The A/D conversion end interrupt (INTAD) is generated for each A/D conversion, and A/D conversion is stopped.

Trigger Analog Input		A/D Conversion Result Register		
ADTRG signal	ANIn	ADCRn		

While the ADCE bit of the ADM0 register is 1, A/D conversion is repeated every time a trigger is input from the ADTRG pin.

This mode is most appropriate for applications in which the results are read after each A/D conversion.

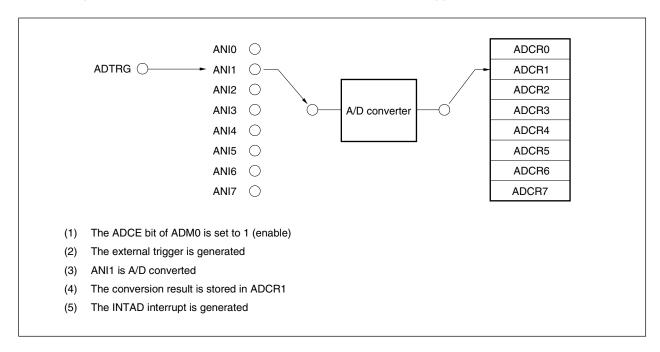

Figure 12-12. Example of 1-Buffer Mode Operation (External Trigger Select: 1 Buffer) (ANI1)

## (2) 4-buffer mode (external trigger select: 4 buffers)

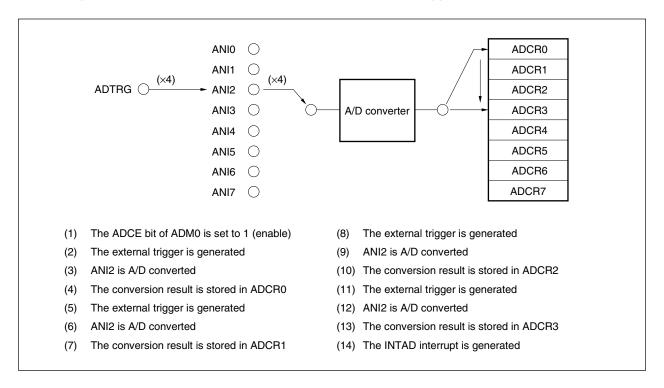

In this mode, one analog input is A/D converted four times using the ADTRG signal as a trigger and the results are stored in the ADCRn register. The A/D conversion end interrupt (INTAD) is generated and A/D conversion is stopped after the 4th A/D conversion.

Trigger	Analog Input	A/D Conversion Result Register
ADTRG signal	ANI0 to ANI3	ADCR0 (1st time)
		ADCR1 (2nd time)
		ADCR2 (3rd time)
		ADCR3 (4th time)
	ANI4 to ANI7	ADCR4 (1st time)
		ADCR5 (2nd time)
		ADCR6 (3rd time)
		ADCR7 (4th time)

While the ADCE bit of the ADM0 register is 1, A/D conversion is repeated every time a trigger is input from the ADTRG pin.

This mode is suitable for applications in which the average of the A/D conversion results is calculated.

### 12.7.2 Scan mode operation

In this mode, the analog inputs specified by the ADM2 register are selected sequentially from the ANI0 pin using the ADTRG signal as a trigger, and A/D converted. The A/D conversion results are stored in the ADCRn register corresponding to the analog input (n = 0 to 7).

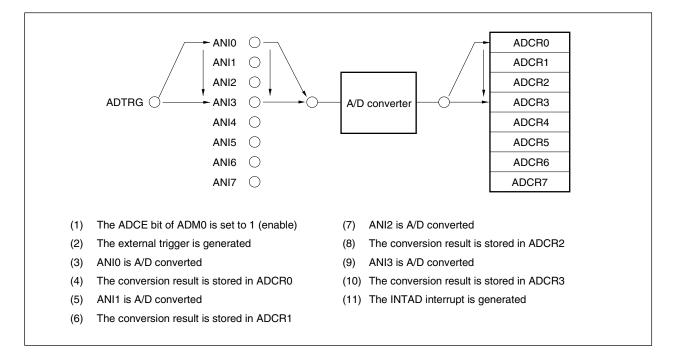

When conversion of all the specified analog inputs has ended, the A/D conversion end interrupt (INTAD) is generated. Unless the ADCE bit of the ADM0 register is cleared to 0 after end of conversion, the A/D converter waits for a trigger. The converter starts A/D conversion from the ANI0 input when a trigger is input to the ADTRG pin again.

Trigger	Analog Input	A/D Conversion Result Register
ADTRG signal	ANI0	ADCR0
	ANI1	ADCR1
	ANI2	ADCR2
	ANI3	ADCR3
	ANI4	ADCR4
	ANI5	ADCR5
	ANI6	ADCR6
	ANI7	ADCR7

When a trigger is input to the ADTRG pin while the ADCE bit of the ADM0 register is 1, A/D conversion is started again.

This is most appropriate for applications in which multiple analog inputs are constantly monitored.

## 12.8 Notes on Operation

#### (1) Stopping conversion operation

When the ADCE bit of the ADM0 register is cleared to 0 during a conversion operation, the conversion operation stops and the conversion results are not stored in the ADCRn register (n = 0 to 7).

#### (2) External/timer trigger interval

Set the interval (input time interval) of the trigger in the external or timer trigger mode longer than the conversion time specified by the FR3 to FR0 bits of the ADM1 register.

#### When 0 < interval ≤ conversion operation time

When the following external trigger or timer trigger is input during a conversion operation, the conversion operation is aborted and the conversion starts according to the last external trigger input or timer trigger input.

When conversion operations are aborted, the conversion results are not stored in the ADCRn register (n = 0 to 7). However, the number of times the trigger has been input is counted. When an interrupt occurs, the values that have been converted are stored in the ADCRn register.

#### (3) Operation in standby mode

#### <1> HALT mode

In this mode, A/D conversion continues. When this mode is released by NMI input or unmasked maskable interrupt input (see **8.6.3 (2) Release of HALT mode**), the ADM0, ADM1, and ADM2 registers and ADCRn register hold the value (n = 0 to 7).

#### <2> IDLE mode, software STOP mode

As clock supply to the A/D converter is stopped, no conversion operations are performed.

When these modes are released by NMI input, the ADM0, ADM1, and ADM2 registers and the ADCRn register hold the value (n = 0 to 7). However, when the IDLE or software STOP mode is set during a conversion operation, the conversion operation is stopped. At this time, if the mode released by NMI input or unmasked maskable interrupt input (see 8.6.4 (2) Release of IDLE mode, 8.6.5 (2) Release of software STOP mode), the conversion operation resumes, but the conversion result written to the ADCRn register will become undefined.

#### (4) Compare match interrupt in timer trigger mode

The compare register's match interrupt becomes an A/D conversion start trigger and starts the conversion operation. When this happens, the compare register's match interrupt also functions as a compare register match interrupt for the CPU. In order to prevent match interrupts from the compare register for the CPU, disable interrupts using the interrupt mask bits (CCC4MK0, CCC4MK1, CCC5MK0, CCC5MK1) of the interrupt control register (CCC4IC0, CCC4IC1, CCC5IC0, CCC5IC1).

### (5) Input range of ANI0 to ANI7

Use the input voltage at ANI0 to ANI7 within the specified range. If a voltage outside the range of  $AV_{\text{REFP}}$  and  $AV_{\text{REFM}}$  is input to any of these pins (even within the absolute maximum rating range), the converted value of the channel is undefined. In addition, the converted value of the other channels may also be affected.

# (6) Conflict

<1> Conflict between writing A/D conversion result registers (ADCRn, ADCRnH) at end of conversion and reading ADCRn and ADCRnH registers by instruction

Reading the ADCRn and ADCRnH registers takes precedence. After these registers have been read, the new conversion result is written to the ADCRn and ADCRnH registers.

<2> Conflict between writing ADCRn and ADCRnH at end of conversion and input of external trigger signal

The external trigger signal is not accepted during A/D conversion. Therefore, it is not accepted while ADCRn and ADCRnH are being written.

<3> Conflict between writing ADCRn and ADCRnH at end of conversion and writing A/D converter mode register 1 (ADM1) or A/D converter mode register 2 (ADM2) If ADM1 or ADM2 is written immediately after ADCRn and ADCRnH have been written on completion of A/D conversion, the conversion result is written to the ADCRn and ADCRnH registers, but the A/D

A/D conversion, the conversion result is written to the ADCRn and ADCRnH registers, but the conversion end interrupt (INTAD) may not occur depending on the timing.

# 12.9 How to Read A/D Converter Characteristics Table

Here, special terms unique to the A/D converter are explained.

### (1) Resolution

This is the minimum analog input voltage that can be identified. That is, the percentage of the analog input voltage per bit of digital output is called 1LSB (Least Significant Bit). The percentage of 1LSB with respect to the full scale is expressed by %FSR (Full Scale Range). %FSR indicates the ratio of analog input voltage that can be converted as a percentage, and is always represented by the following formula regardless of the resolution.

1%FSR = (Max. value of analog input voltage that can be converted – Min. value of analog input voltage that can be converted)/100

= (AVREFP - AVREFM)/100

1LSB is as follows when the resolution is 10 bits.

 $1LSB = 1/2^{10} = 1/1024$ = 0.098%FSR

Accuracy has no relation to resolution, but is determined by overall error.

# (2) Overall error

This shows the maximum error value between the actual measured value and the theoretical value.

Zero-scale error, full-scale error, linearity error and errors that are combinations of these express the overall error.

Note that the quantization error is not included in the overall error in the characteristics table.

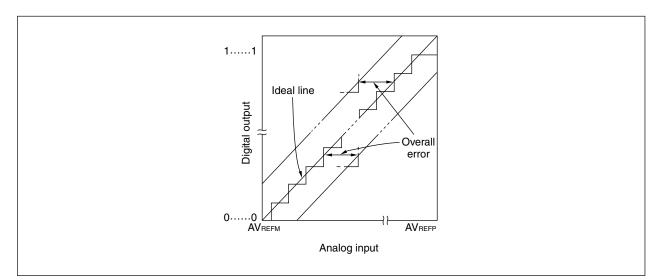

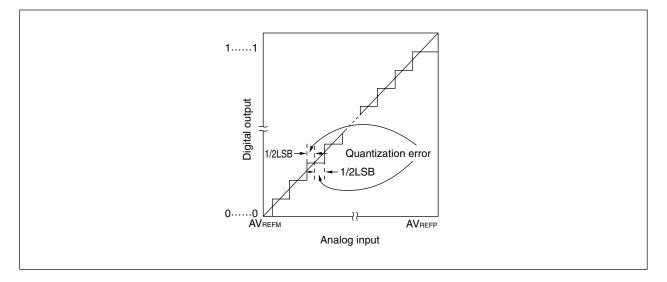

Figure 12-15. Overall Error

# (3) Quantization error

When analog values are converted to digital values, a  $\pm 1/2$ LSB error naturally occurs. In an A/D converter, an analog input voltage in a range of  $\pm 1/2$ LSB is converted to the same digital code, so a quantization error cannot be avoided.

Note that the quantization error is not included in the overall error, zero-scale error, full-scale error, integral linearity error, and differential linearity error in the characteristics table.

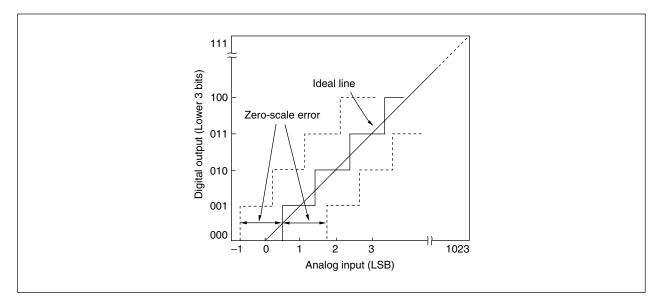

#### (4) Zero-scale error

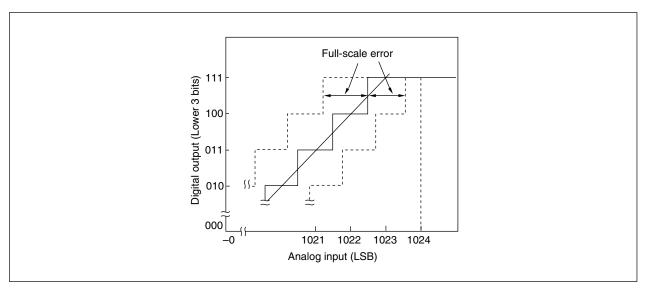

This shows the difference between the actual measurement value of the analog input voltage and the theoretical value (1/2 LSB) when the digital output changes from 0.....000 to 0.....001.

Figure 12-17. Zero-Scale Error

# (5) Full-scale error

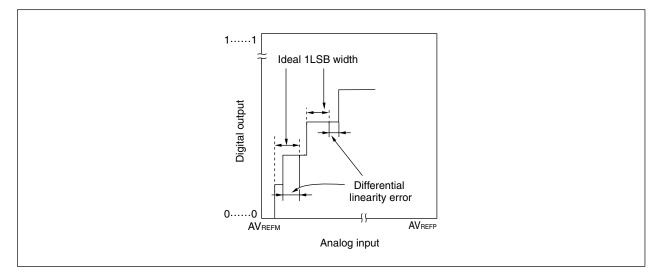

This shows the difference between the actual measurement value of the analog input voltage and the theoretical value (3/2LSB) when the digital output changes from 1.....110 to 1.....111.

## (6) Differential linearity error

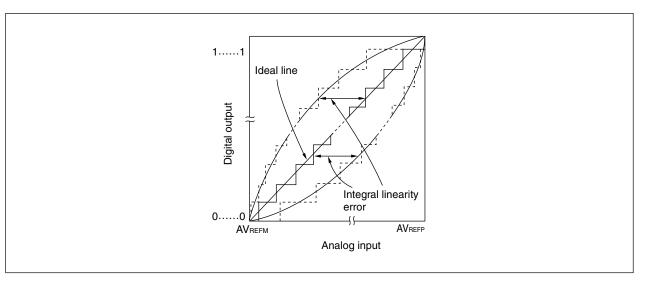

While the ideal width of code output is 1LSB, this indicates the difference between the actual measurement value and the ideal value.

# (7) Integral linearity error

This shows the degree to which the conversion characteristics deviate from the ideal linear relationship. It expresses the maximum value of the difference between the actual measurement value and the ideal straight line when the zero-scale error and full-scale error are 0.

## (8) Conversion time

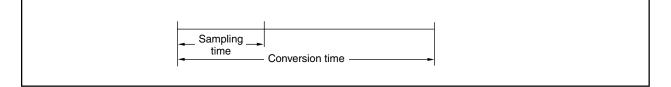

This expresses the time from when the analog input voltage was applied to the time when the digital output was obtained.

The sampling time is included in the conversion time in the characteristics table.

## (9) Sampling time

This is the time the analog switch is turned on for the analog voltage to be sampled by the sample & hold circuit.

## **CHAPTER 13 PWM UNIT**

## 13.1 Features

- PWMn: 2 channels
- 12- to 16-bit accuracy selectable
- Minimization of low-pass filter size due to main pulse + ancillary pulse configuration Main pulse 4/5/6/7/8 bits
   Ancillary pulse 8 bits
- Repeat frequency: 129 kHz to 2 MHz (fpwmc = 33 MHz)
- Selecting pulse width rewrite period: Every 1 pulse/256 pulses
- Active level of PWM output pulse selectable
- PWM operating clock (fpwmc): fx/4, fx/8, fx/16, or fx/32 selectable

Remarks 1. n = 0, 1

- **2.** fpwmc: PWM operating clock
  - fx: Main clock

## 13.2 Configuration

PWMn has a PWM output configuration of 256 main pulses and sets the active-level width using modulo H register n.

(1) Prescaler

The prescaler divides fx to generate the PWM operating clock (f<sub>PWMC</sub>). The output frequency of the prescaler can be selected from fx/4, fx/8, fx/16, and fx/32, by using the CKSPn1 and CKSPn0 bits of the PWMCn register (n = 0, 1).

### (2) Reload controller

The reload controller controls reloading of the modulo register value.

The reload timing (PWM pulse width rewrite period) can be selected from  $2^{x/f_{PWMC}}$  or  $2^{x+8/f_{PWMC}}$  by using the SYNn bit of the PWMCn register (n = 0, 1, x = 4 to 8 (main pulse bit length)).

## (3) Main pulse generator/output controller

This circuit controls the output timing of the main pulse. It generates the main pulse from the reload signal generated by the reload controller, according to the value of modulo H register n (n = 0, 1).

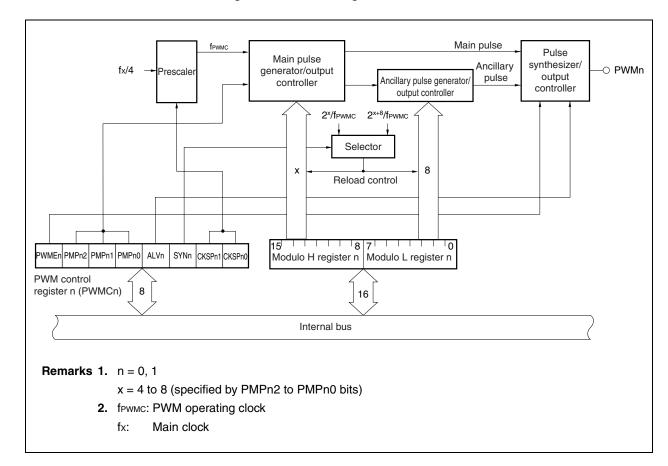

## (4) Ancillary pulse generator/output controller

This circuit controls the output timing of the ancillary pulse. It generates an ancillary pulse from the reload signal generated by the reload controller, according to the value of modulo L register n (n = 0, 1).

# (5) Pulse synthesizer/output controller

★

This circuit controls the timing of the PWM pulse signal output by synthesizing the main pulse and ancillary pulse.

# **13.3 Control Registers**

# (1) PWM control registers 0 and 1 (PWMC0 and PWMC1)

PWMCn is a register that controls PWMn (n = 0, 1). These registers can be read or written in 8-bit or 1-bit units.

- Cautions 1. Do not change the setting of the PMPn2 to PMPn0, SYNn, CKSPn1, and CKSPn0 bits during PWM operation (when PWMEn bit = 1). Otherwise, the operation cannot be guaranteed.
  - Note that, if the setting of the ALVn bit is changed during PWM operation (when PWMEn bit = 1), noise may be generated.

## (2) PWM modulo registers 0 and 1 (PWM0 and PWM1)

These 16-bit registers determine the pulse width of the PWM pulse.

These registers can be read or written in 16-bit units.

If the higher 8 bits of the PWMn register are used as a PWMHn register and the lower 8 bits are used as a PWMLn register, these registers can be read or written in 8-bit units.

# <1> Modulo H register n (PWMHn): Bits 15 to 8

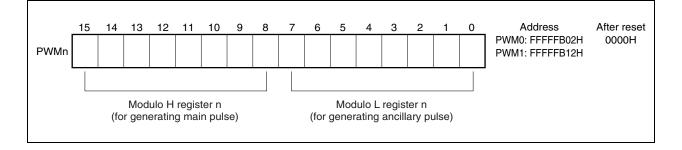

This register specifies the active level of the main pulse.

The data of the active level width of only the bit length specified by the PMPn2 to PMPn0 bits of the PWMCn register is valid. If the counter length is set to 4 to 7 bits by the PMPn2 to PMPn0 bits, data input to the higher bits is invalid.

# <2> Modulo L register n (PWMLn): Bits 7 to 0

This register adjusts the timing of the ancillary pulse for fine tuning (see Figure 13-2).

A value of 0000H to FFFFH can be set to the PWMn register, and the PWM output changed linearly. If a value of 0000H is set, the inactive level is held. If the value is FFFFH, the PWM output becomes inactive for one ancillary pulse (1/fPWMC) in one rewrite cycle (2<sup>16</sup>/fPWMC) (see **Figure 13-3**).

# 13.4 Operation

## 13.4.1 PWM basic operation

PWMn is divided into 256 parts, each of which is called a main pulse. Each main pulse has 4- to 8-bit accuracy. PWMn realizes a signal with an accuracy of 12 to 16 bits by synthesizing the required number of main pulses and an ancillary pulse with a pulse width of one clock.

The main pulse is set by the PMPn2 to PMPn0 bits of PWM control register n (PWMCn), and the pulse width is determined by the value of modulo H register n (valid number of bits). The repeat cycle of the PWM pulse output is the operating clock cycle (fPWMC) of PWMn specified by the CKSPn1 and CKSPn0 bits of the PWMCn register divided by 2<sup>x</sup> (fPWMC/2<sup>x</sup>).

Of the 256 main pulses, the ancillary pulses are generated only for the main pulses of the set number specified by modulo L register n. The pulse width is 1/fpwmc.

The logical sum of the main pulse and the ancillary pulse is output as the PWM pulse signal. Therefore, the average value of 256 PWM pulse signals is the PWM pulse signal with a resolution of 12 to 16 bits.

The duty factor of the output PWM pulse is determined as follows, by the value set to modulo H register n of PWM modulo register n (PWM0 or PWM1).

### (1) If ancillary pulse is not generated

Duty of output PWM pulse =  $\frac{\text{(Value of modulo H register n)}}{2^{x}}$ 

#### (2) If ancillary pulse is generated

Duty of output PWM pulse =  $\frac{\text{(Value of modulo H register n)} + 1}{2^{x}}$ 

**Remark** x = 4 to 8 (bit length of main pulse)

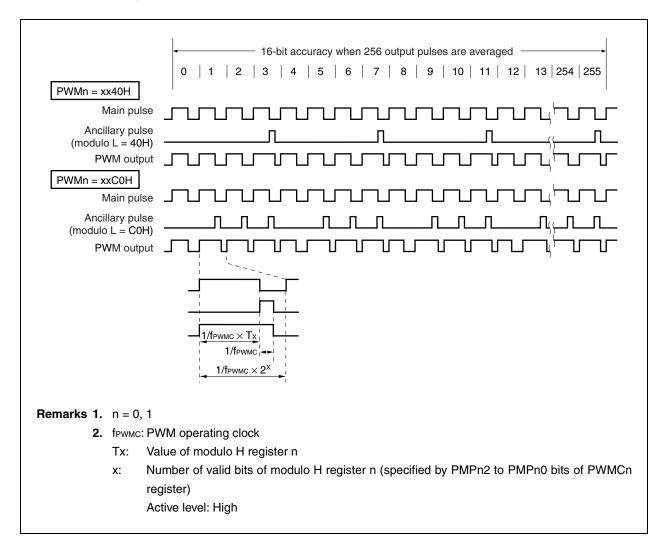

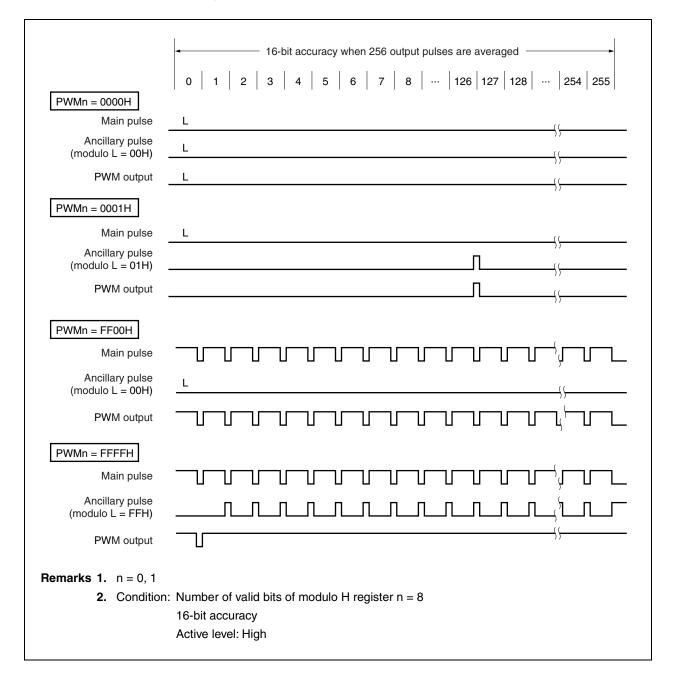

Figure 13-3. Example of PWM Output Operation

### 13.4.2 Starting/stopping PWM operation

To output a PWM pulse, set data to PWM modulo register n (PWMn) and then set the PWMEn bit of PWM control register n (PWMCn) to 1 (n = 0, 1).

As a result, the PWM output pin outputs a PWM pulse of the active level specified by the ALVn bit of the PWMCn register.

When the PWMEn bit of the PWMCn register is cleared to 0, the PWM output unit immediately stops the PWM output operation, and the PWM output pin becomes inactive.

### (1) Setting for starting PWM operation

Before starting the operation of PWMn (when PWMEn bit of PWMCn register = 0), be sure to initialize the following registers.

- PMCDH, PFCDH registers: Set the control mode.
- PWMn register: Set the pulse width.
- PWMCn register:

CKSPn1 and CKSPn0 bits:	Specify the operating clock (fPWMC) (fx/4, fx/8,
	fx/16, fx/32)
PMPn2 to PMPn0 bits:	Specify the bit length (x) of the main pulse.
ALVn bit:	Specify the active level of the PWM pulse.
SYNn bit:	Specify the PWM pulse width rewrite period.

- Cautions 1. Do not change the setting of the PMPn2 to PMPn0, SYNn, CKSPn1, and CKSPn0 bits when PWMEn bit of the PWMCn register = 1. Otherwise, the operation cannot be guaranteed.
  - 2. Note that, if the setting of the ALVn bit is changed during PWM operation (when PWMEn bit = 1), noise may be generated.

**Remark** n = 0, 1

When the PWMEn bit of the PWMCn register is set, PWMn starts operating. Immediately after PWMn has started operating, however, the PWM pin maintains the status of the port mode (inactive level) until the reload signal of the PWMn register is generated. After the operation has been started, the PWM output becomes active when the reload signal is generated, regardless of the setting of the SYNn bit (PWMn = other than 00xxH). If the timing of rewriting the pulse width is set to  $2^{x+8}$  (long period: SYNn bit = 0), the operation is started up to  $2^{x+8}$ /fpwmc after the PWMEn bit has been set. The PWMn register can be rewritten even during PWM output.

# (2) Setting for stopping PWM operation

When the PWMEn bit of the PWMCn register (n = 0, 1) is cleared to 0, the PWM operation is immediately stopped, and the PWM output becomes inactive immediately.

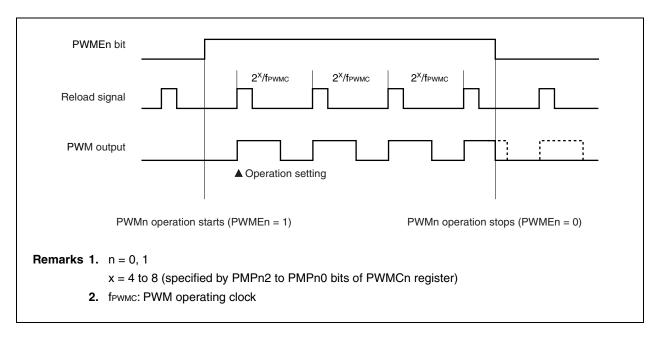

Figure 13-4. PWM Operation Timing

## 13.4.3 Setting active level of PWM pulse

The ALVn bit of PWM control register n (PWMCn) specifies the active level of the PWM pulse output from the PWM output pin (n = 0, 1).

If the ALVn bit is set to 1, an active-high pulse is output; if it is cleared to 0, an active-low pulse is output.

If the ALVn bit is rewritten, the active level of PWM output is immediately changed. The figure below shows the setting of the active level of PWM output and pin status.

Regardless of the setting of the PWMEn bit (which enables or disables PWM), the active level of PWM output can be changed by manipulating the ALVn bit.

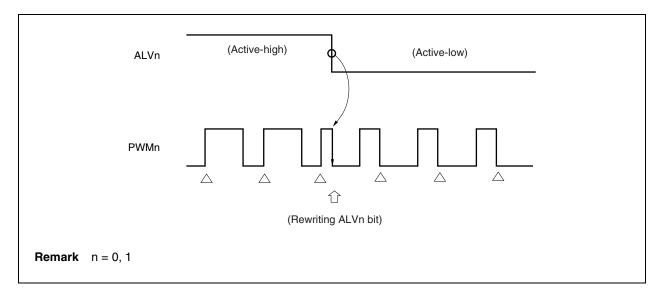

Figure 13-5. Setting Active Level of PWM Output

## 13.4.4 Specifying PWM pulse width rewrite period

PWM output is started and the pulse width is changed every 256 cycles of the PWM pulse  $(2^{x+6}/f_{PWMC})$  or every one PWM cycle  $(2^{x}/f_{PWMC})$ . This PWM pulse width rewrite period is specified by the SYNn bit of the PWMCn register (n = 0, 1).

When the SYNn bit is cleared to 0, the pulse width is changed every 256 PWM pulse cycles  $(2^{x+8}/f_{PWMC})$  (long period). Therefore, it takes up to  $2^{x+8}$  clocks to output a pulse of the width corresponding to the data written to the PWMn register.

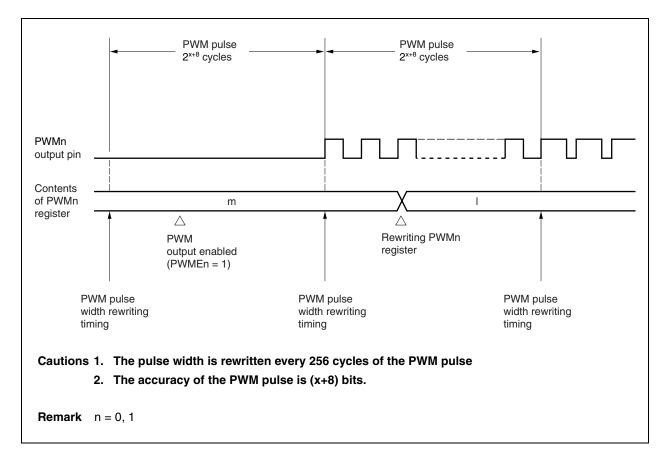

An example of the PWM output timing at this time is shown in Figure 13-6.

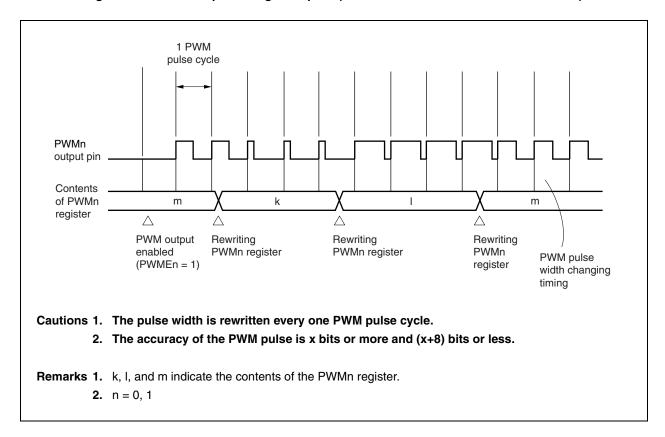

When the SYNn bit is set to 1, the pulse width is changed every one PWM pulse cycle ( $2^{x}/f_{PWMC}$ ) (short period). In this case, it takes up to  $2^{x}$  clocks to output a pulse of the width corresponding to the data written to the PWMn register.

If the PWM pulse rewrite period is specified to be every  $2^{x/f_{PWMC}}$  (if the SYNn bit is set to 1), the accuracy of the PWM pulse is x bits or more and (x+8) bits or less, or is lower than the accuracy when the rewrite cycle is set to  $2^{x+8}/f_{PWMC}$ . However, the response speed improves because the repeat cycle increases.

Figure 13-7 shows an example of the PWM output timing where the rewrite timing is 2<sup>x</sup>/fpwmc.

## 13.4.5 Repeat cycle

The following table shows the repeat cycle of PWMn (n = 0, 1).

\*

# 14.1 Features

- Input-only ports: 1
   I/O ports: 77
- Function alternately as other peripheral I/O pins.
- It is possible to specify input and output in 1-bit units.

# 14.2 Port Configuration

The V850E/ME2 incorporates a total of 78 input/output ports (including 1 input-only port) labeled ports 1, 2, 5 to 7, AL, AH, DH, CS, CT, CM, and CD. The port configuration is shown below.

# (1) Function of each port

The port functions of this product are shown below.

8-bit and 1-bit operations are possible on all ports, allowing various kinds of control to be performed. In addition to their port functions, these pins also function as on-chip peripheral I/O input/output pins in the control mode. For the block types of each port, see **(3)** Block diagram of port.

Port CM	PCM0 to PCM5	6-bit I/O	Wait insertion signal input External bus interface control signal I/O Self-refresh request signal input A/D converter external trigger input	C-1, D-1, D-2, F-5
Port CD	PCD0 to PCD3	4-bit I/O	External bus interface control signal output Bus clock output	D-1, D-2

- Cautions 1. When switching the mode of a port that functions as an output or I/O pin to control mode, be sure to follow the procedure below.
  - <1> Set the inactive level of the signals output in control mode to the appropriate bits in port n (n = 1, 2, 5 to 7, AL, AH, DH, CS, CT, CM, and CD).
  - <2> The mode is switched to control mode by the port n mode control register (PMCn).

If <1> above is not performed, the contents of port n may be output for a moment when the mode is switched from port mode to control mode.

2. To manipulate a port by using a bit manipulation instruction (SET1, CLR1, or NOT1), read the port in byte units, process the data of only the bit to be manipulated, and then write back the byte data to the port after conversion. In the case of a port having a mixture of input and output pins, the contents of the output latch are written over bits other than the bit to be manipulated. Consequently, the output latch of the input pin is undefined (in the input mode, however, the pin status does not change because the output buffer is turned off).

To change the port mode from the input to the output mode, therefore, set an expected output value to the corresponding bits, and then change the mode to the output mode. The same applies to a port that has both a control mode and an output mode.

# 14.3 Port Pin Functions

## 14.3.1 Port 1

Port 1 is a 4-bit I/O port that can be set to the input or output mode in 1-bit units.

	defined
Bit position Bit name Function	
3 to 0 P1n I/O port (n = 3 to 0)	

In addition to their function as port pins, the port 1 pins can also operate as serial interface I/O (CSI30, UARTB0), USB clock signal input, and external interrupt request input in the control mode.

	Port	Alternate Function	Remark	Block Type
Port 1	P10	INTP10/UCLK	External interrupt input/USB clock signal input	F-3

	P12	SI0/RXD0	Serial interface (CSI30) I/O/	F-1
	P13	SO0/TXD0	serial interface (UARTB0) I/O	J-1

The port 1 I/O mode setting is performed by the port 1 mode register (PM1), and the control mode setting is performed by the port 1 mode control register (PMC1) and port 1 function control register (PFC1).

The valid edges of the INTP10 and INTP11 pins can be selected by program. The levels to be detected can also be selected.

External interrupt rising edge specification register 1 (INTR1) and external interrupt falling edge specification register 1 (INTF1) are used to specify the valid edge and level detection.

(a) External interrupt rising edge specification register 1 (INTR1) and external interrupt falling edge specification register 1 (INTF1)

These registers are used to specify the trigger mode of the external interrupt requests (INTP10 and INTP11) from external pins.

The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTF10 and INTR10 bits: INTP10
- INTF11 and INTR11 bits: INTP11

The valid edge can be independently selected from the rising edge, falling edge, and both rising and falling edges.

Both the registers can be read or written in 8-bit or 1-bit units.

Caution Before setting the trigger mode of the INTP10 and INTP11 pins, set the PMC1 register. If the PMC1 register is set after the INTR1 and INTF1 registers have been set, an illegal interrupt may occur when the PMC1 register is set.

- **Notes 1.** The level of the INTP1n pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the P1IFn bit (n = 0, 1). Consequently, even when the CPU acknowledges the interrupt and the P1IFn bit of the interrupt control register (P1ICn) is automatically cleared to 0, the P1IFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the INTP1n pin of the external device inactive in the interrupt servicing routine, and forcibly clear the P1IFn bit to 0.
  - 2. If a level-detected interrupt request (INTP1n) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request (INTP1n) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt (INTP1n) is held pending (n = 0, 1). To not acknowledge the interrupt request of INTP1n, clear the P1IFn bit of the interrupt control register.

## 14.3.6 Port AL

Port AL (PAL) is a 16-bit I/O port that can be set to the input or output mode in 1-bit units.

When the higher 8 bits of port AL are used as port ALH (PALH) and the lower 8 bits as port ALL (PALL), port AL becomes two 8-bit ports that can be set in the input or output mode in 1-bit units.

In addition to their functions as port pins, in the control mode, the port AL pins operate as an address bus for when the memory is externally expanded and external interrupt request input.

	Port	Alternate Function	Remark	Block Type
Port AL	PAL0, PAL1	INTPL0/A0, INTPL1/A1	Address bus when memory expanded/ external interrupt request input	G-3

\*

The port AL I/O mode setting is performed by the port AL mode register (PMAL), and control mode setting is performed by port AL mode control register L (PMCALL) and the port AL function control register (PFCAL).

#### (a) Port AL mode register (PMAL)

The port AL mode register (PMAL) can be read or written in 16-bit units.

When using the higher 8 bits of PMAL as port AL mode register H (PMALH) and the lower 8 bits as port AL mode register L (PMALL), the PMALH register is read-only in 8-bit or 1-bit units, and the PMALL register can be read or written in 8-bit or 1-bit units.

#### (b) Port AL mode control register (PMCAL)

The port AL mode control register (PMCAL) can be read or written in 16-bit units.

When using the higher 8 bits of PMCAL as port AL mode control register H (PMCALH) and the lower 8 bits as port AL mode control register L (PMCALL), the PMCALH register is read-only in 8-bit or 1-bit units, and the PMCALL register can be read or written in 8-bit or 1-bit units.

#### (3) Selecting interrupt trigger mode

The valid edges of the  $\overline{INTPLn}$  pin can be selected by program (n = 0, 1). The level detection of the  $\overline{INTPLn}$  pin can also be selected.

External interrupt rising edge specification register AL (INTRAL) and external interrupt falling edge specification register AL (INTFAL) are used to specify the valid edge and level detection.

# (a) External interrupt rising edge specification register AL (INTRAL) and external interrupt falling edge specification register AL (INTFAL)

These registers are used to specify the trigger mode of an external interrupt request (INTPLn) from an external pin (n = 0, 1). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTFAL0 and INTRAL0 bits: INTPAL0
- INTFAL1 and INTRAL1 bits: INTPAL1

The rising edge, falling edge, or both the rising and falling edges can be specified as the valid edge of the INTPLn pin, independently for each pin.

Both the registers can be read or written in 8-bit or 1-bit units.

#### Caution Before setting the trigger mode, set the PMCAL register.

If the PMCAL register is set after the INTRAL and INTFAL registers have been set, an illegal interrupt may occur when the PMCAL register is set.

_	7	6	5	4	3	2	1	0	Address	After reset	
INTRAL	0	0	0	0	0	0	INTRAL1	INTRAL0	FFFFFC30H	03H	
INTFAL	0	0	 0	0	0	0	INTFAL1	INTFAL0	FFFFC10H	00H	
Bit positi	on	Bit name					Function				
1, 0		NTFALn,	Specify trigger mode of INTPLn pin.								
		NTRALn (n = 0, 1)	INTFALn INTRALn			Operation					
		(1 – 0, 1)	0 0 Falling edge								
			(	D	1	Rising ed	ge				
				1	0	Level dete	ection (low-le	evel detection	n) <sup>Notes 1, 2</sup>		
				1	1	Both rising	g and falling	edges			
						•	0	0			

- **Notes 1.** The level of the INTPLn pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the PLIFn bit (n = 0, 1). Consequently, even when the CPU acknowledges the interrupt and the PLIFn bit of the interrupt control register (PLICn) is automatically cleared to 0, the PLIFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the INTPLn pin of the external device inactive in the interrupt servicing routine, and forcibly clear the PLIFn bit to 0.
  - 2. If a level-detected interrupt request (INTPLn) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request (INTPLn) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt (INTPLn) is held pending (n = 0, 1). To not acknowledge the interrupt request of INTPLn, clear the PLIFn bit of the interrupt control register.

## 14.3.7 Port AH

Port AH (PAH) is a 10-bit I/O port that can be set in the input or output mode in 1-bit units.

When the higher 8 bits of port AH are used as port AHH (PAHH) and the lower 8 bits as port AHL (PAHL), port AH becomes two 8-bit ports that can be set in the input or output mode in 1-bit units.

The port AH I/O mode setting is performed by the port AH mode register (PMAH), and the control mode setting is performed by the port AH mode control register (PMCAH).

## (a) Port AH mode register (PMAH)

The port AH mode register (PMAH) can be read or written in 16-bit units.

If the higher 8 bits of PMAH are used as port AH mode register H (PMAHH), and the lower 8 bits as port AH mode register L (PMAHL), these two 8-bit port mode registers can be read or written in 8-bit or 1-bit units.

#### (3) Selecting interrupt trigger mode

The valid edges of the  $\overline{\text{INTPDn}}$  pin can be selected by program (n = 0 to 15). The level detection of the  $\overline{\text{INTPDn}}$  pin can also be selected.

External interrupt rising edge specification register DH (INTRDH) and external interrupt falling edge specification register DH (INTFDH) are used to specify the valid edge and level detection.

# (a) External interrupt rising edge specification register DH (INTRDH) and external interrupt falling edge specification register DH (INTFDH)

These registers are used to specify the trigger mode of an external interrupt request (INTPDn) from an external pin (n = 0 to 15). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTFDH0 and INTRDH0 bits: INTPD0
- INTFDH1 and INTRDH1 bits: INTPD1
- INTFDH2 and INTRDH2 bits: INTPD2
- INTFDH3 and INTRDH3 bits: INTPD3
- INTFDH4 and INTRDH4 bits: INTPD4
- INTFDH5 and INTRDH5 bits: INTPD5
- INTFDH6 and INTRDH6 bits: INTPD6
- INTFDH7 and INTRDH7 bits: INTPD7
- INTFDH8 and INTRDH8 bits: INTPD8
- INTFDH9 and INTRDH9 bits: INTPD9
- INTFDH10 and INTRDH10 bits: INTPD10
- INTFDH11 and INTRDH11 bits: INTPD11
- INTFDH12 and INTRDH12 bits: INTPD12
- INTFDH13 and INTRDH13 bits: INTPD13
- INTFDH14 and INTRDH14 bits: INTPD14
- INTFDH15 and INTRDH15 bits: INTPD15

The rising edge, falling edge, or both the rising and falling edges can be specified as the valid edge of the INTPDn pin, independently for each pin.

INTRDH and INTFDH registers can be read or written in 16-bit units.

When the higher 8 bits of the INTRDH and INTFDH registers are used as INTRDHH and INTFDHH registers, and the lower 8 bits as INTRDHL and INTFDHL registers, these registers can be read or written in 8-bit or 1-bit units.

#### Caution Before setting the trigger mode, set the PMCDH register.

If the PMCDH register is set after the INTRDH and INTFDH registers have been set, an illegal interrupt may occur when the PMCDH register is set.

- **Notes 1.** The level of the INTPDn pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the PDIFn bit (n = 0 to 15). Consequently, even when the CPU acknowledges the interrupt and the PDIFn bit of the interrupt control register (PDICn) is automatically cleared to 0, the PDIFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the INTPDn pin of the external device inactive in the interrupt servicing routine, and forcibly clear the PDIFn bit to 0.
  - 2. If a level-detected interrupt request (INTPDn) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request (INTPDn) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt (INTPDn) is held pending (n = 0 to 15). To not acknowledge the interrupt request of INTPDn, clear the PDIFn bit of the interrupt control register.

## 14.3.9 Port CS

Port CS (PCS) is an 8-bit I/O port that can be set to the input or output mode in 1-bit units.

Function

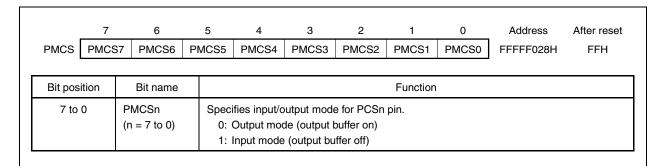

In addition to their function as port pins, in the control mode, the port pins can also operate as the chip select signal outputs when memory is externally expanded and the read/write strobe signal output to an external I/O.

This register can be read or written in 8-bit or 1-bit units.

- Cautions 1. When the port mode is specified by the port CT mode control register (PMCCT), the setting of this register becomes invalid.
  - 2. The timing of the xxDQM signal differs between when the  $\overline{xxWR}$  output mode/xxDQM output mode is selected and when the  $\overline{xxBE}$  output mode/xxDQM output mode is selected. However, if either mode is selected, no problems occur when connecting to SDRAM. For the output timing of the xxDQM signal, refer to the timing diagrams (Figures 5-9 to 5-11) in 5.3.5 SDRAM access (xx = UU, UL, LU, LL).

#### 14.5 Operation of Port Function

The operation of a port differs depending on whether it is set in the input or output mode, as follows.

#### 14.5.1 Writing to I/O port

#### (1) In output mode

A value can be written to the output latch (Pn) by writing it to the port n register (Pn). The contents of the output latch are output from the pin.

Once data is written to the output latch, it is held until new data is written to the output latch.

#### (2) In input mode

A value can be written to the output latch (Pn) by writing it to the port n register (Pn). However, the status of the pin does not change because the output buffer is off.

Once data is written to the output latch, it is held until new data is written to the output latch.

Caution A bit manipulation instruction (CLR1, SET1, NOT1) manipulates 1 bit but accesses a port in 8-bit units. If this instruction is executed to manipulate a port with a mixture of input and output bits, the contents of the output latch of a pin set in the input mode, in addition to the bit to be manipulated, are overwritten to the current input pin status and become undefined.

#### 14.5.2 Reading from I/O port

#### (1) In output mode

The contents of the output latch (Pn) can be read by reading the port n register (Pn). The contents of the output latch do not change.

#### (2) In input mode

The status of the pin can be read by reading the port n register (Pn). The contents of the output latch (Pn) do not change.

#### 14.5.3 Output status of alternate function in control mode

The status of a port pin is not dependent upon the setting of the PMCn register and can be read by setting the port n mode register (PMn) to the input mode. If the PMn register is set to the output mode, the value of the port n register (Pn) can be read in the port mode, and the output status of the alternate function can be read in the control mode.

## 14.6 Noise Eliminator

2. The noise eliminator is valid only in the control mode.

Cautions 1. The above non-maskable and maskable interrupt pins are used to release the standby mode. A timing circuit that controls the clock is not employed because the internal system clock is stopped in the standby mode.

#### 14.6.2 A/D converter input pin

The following timing controller used to secure the noise elimination time is provided for the ADTRG pin. An input signal that changes within the noise elimination time is not internally acknowledged.

#### Caution The noise eliminator is valid only in the control mode.

#### 14.6.3 Timer C and timer ENC1 input pins

The following noise filter that operates via clock sampling is provided for the pins of timers C and ENC1 that operate when the valid edge is input. Input signals that change within the noise elimination time are not internally acknowledged.

Table 14-3. Noise Elimination Time of Timer C and Timer ENC1 Input Pins

- Cautions 1. The noise filter of the above pins cannot acknowledge an input signal when the CPU clock is stopped because it uses clock sampling.
  - 2. The noise eliminator is valid only in the control mode.

## (1) Noise elimination width setting registers C0 to C3 (NCWC0 to NCWC3)

These registers are used to set the noise elimination width of the digital noise filter of the timer C input pins. These registers can be read or written in 8-bit units.

Be sure to clear bits 7 to 2 to 0. If they are set to 1, the operation is not guaranteed.

## (2) Noise elimination width setting registers 10, 11 (NCW10, NCW11)

These registers are used to set the noise elimination width of the digital noise filter of the timer ENC1 input pins.

These registers can be read or written in 8-bit units.

- Cautions 1. Whether the signal is input through or inverted can be specified for each of the INTP1n0/TCUD1n and TIUD1n pins. The noise elimination width set by the NCFn, NCC1n, and NCC0n bits is for each timer and cannot be changed for each pin.
  - 2. The setting of the SRTCn bit is valid even when the INTP1n0/TCUD1n pin is used as a capture trigger (INTP1n0).

#### **CHAPTER 15 RESET FUNCTIONS**

### 15.1 Overview

- Reset function by RESET input
- Forced reset function by DCU (See CHAPTER 16 DEBUG FUNCTION (DCU).)
- Low level is input to the RESET pin for 100 μs min. If an oscillation stabilization time of 100 μs or longer is necessary, secure the low level for as long as the necessary oscillation stabilization time.
- Reset generator (RG) eliminates noise from the RESET pin.

#### 15.2 Configuration

During a system reset, most pins (all excluding the BUSCLK, RESET, X2, EVDD, EVss, IVDD, IVss, PLLVDD, PLLVss, OSCVDD, OSCVss, UVDD, AVDD, AVREFP, AVREFM, and AVss pins) enter the high-impedance state.

Therefore, a pull-up (or pull-down) resistor must be connected to each pin of the address bus, data bus, and external bus control signals. If no resistor is connected, external memory may be destroyed when these pins enter the high-impedance state.

For the same reason, the output signals of the on-chip peripheral I/O functions and other output ports should be handled in the same manner.

### 15.3 Operation

When a low-level signal is input to the RESET pin, a system reset is effected and each on-chip hardware is initialized.

When the RESET pin level changes from low to high, the reset state is released and the CPU starts program execution using OSC output clock (Fx). Register contents must be initialized as required in the program.

When the reset signal is cleared, the oscillation stabilization time is not inserted. When the  $\overline{\text{RESET}}$  signal is to be input (reset input on power application or reset input when the software STOP mode is released) while the clock oscillator is stopped, therefore, a low-level width longer than the oscillation stabilization time (100  $\mu$ s min.) must be secured at the  $\overline{\text{RESET}}$  pin. When the  $\overline{\text{RESET}}$  signal is to be input (reset input when the IDLE mode is released) while the clock oscillator is not stopped, a low level of 100  $\mu$ s min. must be secured at the  $\overline{\text{RESET}}$  pin.

#### CHAPTER 16 DEBUG FUNCTION (DCU)

The debug control unit (DCU) consists of three function units: an execution control unit (RCU) that realizes communication with JTAG and execution of debug processing, a trace control unit (TRCU) that implements trace functions, and a trigger event unit (TEU) that implements event detection functions. On-chip debugging of the V850E/ME2 can be executed by connecting an N-Wire type IE.

## Caution The debug function is supported by the V850E/ME2, but whether this function can be used or not depends on the debugger used.

#### 16.1 Functional Outline

#### 16.1.1 Debug function

## (1) Debug interface

This interface establishes communication with the host machine by using the DRST, DCK, DMS, DDI, and DDO signals, via an N-Wire type IE. The communication specifications of JTAG are used for this interface. It does not support a boundary scan function.

#### (2) On-chip debug

On-chip debugging can be performed if wiring and connectors for debugging are provided on the target system.

Connect an N-Wire type IE to the connector for debugging.

#### (3) Forced reset function

The V850E/ME2 can be forcibly reset.

#### (4) Break reset function

The CPU can be started in the debug mode immediately after resetting the CPU has been cleared.

#### (5) Forced break function

Execution of the user program can be forcibly stopped (however, the handler of the illegal instruction code exception (first address: 00000060H) cannot be used).

#### (6) Debug monitor function

During debugging, a memory space for debugging, different from the user memory space, is used (background monitor format). The user program can be executed starting from any address.

While execution of the user program is stopped, the user resources (such as memory and I/O) can be read/written, and the user program can be downloaded.

## ★ (7) Mask function

- (a) NMI and all maskable interrupt request signals can be masked.
- (b) When the debugger is connected, the RESET pin input on the target board is masked by default (the RESET pin input is masked when the debugger is started after power application to the V850E/ME2). The RESET pin input can be unmasked from the debugger. If a signal is input to the RESET pin during debugging (during RUN execution), however, the following problems may occur.
  - The break function may malfunction. If this happens, restart.
  - Trace data may be illegal before and after RESET pin input. Recovery will occur after the RESET signal has been released.

#### 16.1.2 Trace function

### (1) PC trace (branch trace) function

All branches (transition of processing) that occur during user program execution can be traced. The trace sources can be selected from 12 types of branch sources that are classified by function, and PC trace can be started from execution of an instruction at any address, and the trace source can be changed. Two trace start triggers are available.

#### (2) Data trace function

A data access issued by the CPU to any address can be traced in a range of 1 KB to 4 bytes. Read or written data can be traced, and two data trace points are available. However, a data access issued by the DMAC cannot be traced.

#### (3) Real-time trace mode

Branch and data access can be traced during real-time execution of the user program. The trace packet of the trace source detected is stored in a trace buffer, and output from trace interface pins (TRCCLK, TRCDATA0 to TRCDATA3, and TRCEND) (some trace packets may not be traced if no more trace packets can be stored in the trace buffer).

### (4) Full trace mode (non-real-time trace mode)

All branches and data accesses of the user program can be traced.

In the full trace mode, the pipeline of the CPU is temporarily held and instruction execution is stopped to secure the time of trace data output from trace interface pins, so that all trace packets can be correctly traced.

#### 16.1.3 Event function

#### (1) Instruction event detection function

Event detection (10 events) via size comparison by the execution PC and range event detection (up to four pairs with each pair consisting of two events) of the execution PC can be executed.

If an instruction event source is used as a break source, two breakpoints before execution of the instruction at which an event is detected and eight breakpoints after instruction execution can be detected.

#### (2) Access event detection function

Events can be detected as follows.

- Comparison of access addresses (4 addresses)
- Range of access address (up to two pairs with each pair consisting of two addresses)
- Match or mismatch of access data
- Data of specific bit by masking data
- Access size

An access event source is detected after access. If an access event source is used as a break source, a break occurs after several instructions have been executed after the instruction that issued the access that caused event detection.

#### (3) Sequential event detection function

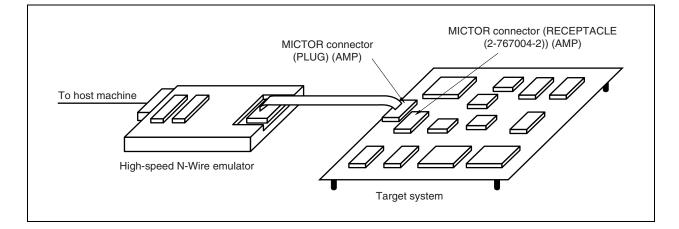

An event can be detected when up to four stages of events have successively occurred or an event that clears successive occurrence of events can be detected.

Sequential events can be counted by using a 12-bit pass counter.

## 16.2 Connection with N-Wire Type IE

A connector for the IE and a connection circuit must be provided on the target system.

		(on larger oystem olde)

**Remark** Cautions are given on the next page.

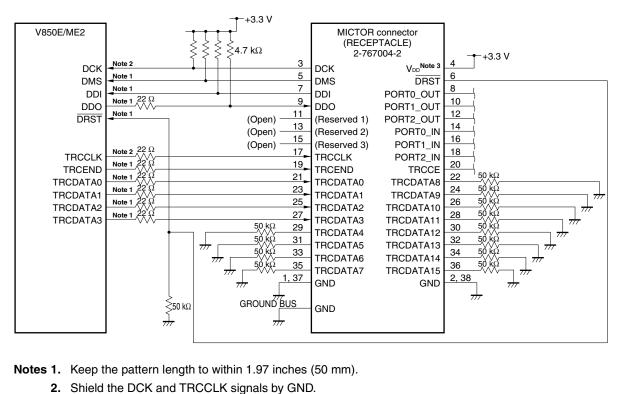

- Cautions 1. The connection of pins not supported by the V850E/ME2 depends on the ICE used.
  - 2. The pattern on the target board must satisfy the following conditions to support high-speed interfacing.
    - Lay out the pattern with the odd pins facing the device (V850E/ME2).
    - Keep the pattern length to within 1.97 inches (50 mm).
    - Shield the clock signal with GND.

#### 16.2.2 Recommended circuit example

## Absolute Maximum Ratings (TA = 25°C)

**Note** Be sure not to exceed the absolute maximum ratings (MAX. value) of each supply voltage.

- Cautions 1. Do not directly connect the output (or I/O) pins of IC products to each other, or to IVDD, EVDD, and GND. Direct connection of the output pins between an IC product and an external circuit is possible, if the output pins can be set to the high-impedance state and the output timing of the external circuit is designed to avoid output conflict.
  - 2. Product quality may suffer if the absolute maximum rating is exceeded even momentarily for any parameter. That is, the absolute maximum ratings are rated values at which the product is on the verge of suffering physical damage, and therefore the product must be used under conditions that ensure that the absolute maximum ratings are not exceeded. The ratings and conditions indicated for DC Characteristics and AC Characteristics represent

the quality assurance range during normal operation.

# (a) Read timing (SDRAM access) (1/2)

Caution If an SRAM (external I/O) cycle that uses the xxWR signal is generated immediately after a read cycle to SDRAM, an SRAM (external I/O) writing error may occur. In this case, set the BCC register to insert an idle state in the SDRAM space or execute a countermeasure using external circuits. However, no writing error occurs in a synchronization design in which the xxWR signal is sampled using BUSCLK.

# CHAPTER 19 RECOMMENDED SOLDERING CONDITIONS

The V850E/ME2 should be soldered and mounted under the following recommended conditions.

For soldering methods and conditions other than those recommended below, contact an NEC Electronics sales representative.

For technical information, see the following website.

### APPENDIX B INSTRUCTION SET LIST

#### **B.1 Conventions**

#### (1) Register symbols used to describe operands

Register Symbol	Explanation	
reg1	General-purpose registers: Used as source registers.	
reg2	General-purpose registers: Used mainly as destination registers. Also used as source register in some instructions.	
reg3	General-purpose registers: Used mainly to store the remainders of division results and the higher order 32 bits of multiplication results.	
bit#3	3-bit data for specifying the bit number	
immX	X bit immediate data	
dispX	X bit displacement data	
regID	System register number	
vector	5-bit data that specifies the trap vector (00H to 1FH)	
сссс	4-bit data that shows the conditions code	
sp	Stack pointer (SP)	
ер	Element pointer (r30)	
listX	X item register list	

## (2) Register symbols used to describe opcodes

Register Symbol	Explanation	
R	1-bit data of a code that specifies reg1 or regID	
r	1-bit data of the code that specifies reg2	
w	1-bit data of the code that specifies reg3	
d	1-bit displacement data	
1	1-bit immediate data (indicates the higher bits of immediate data)	
i	1-bit immediate data	
сссс	4-bit data that shows the condition codes	
CCCC	4-bit data that shows the condition codes of Bcond instruction	
bbb	3-bit data for specifying the bit number	
L	1-bit data that specifies a program register in the register list	
S	1-bit data that specifies a system register in the register list	

#### (3) Register symbols used in operations

Register Symbol	Explanation	
$\leftarrow$	Input for	
GR [ ]	General-purpose register	
SR[]	System register	
zero-extend (n)	Expand n with zeros until word length.	
sign-extend (n)	Expand n with signs until word length.	
load-memory (a, b)	Read size b data from address a.	
store-memory (a, b, c)	Write data b into address a in size c.	
load-memory-bit (a, b)	Read bit b of address a.	
store-memory-bit (a, b, c)	Write c to bit b of address a.	
saturated (n)	Execute saturated processing of n (n is a 2's complement). If, as a result of calculations, $n \ge 7FFFFFFFH$ , let it be 7FFFFFFH. $n \le 80000000H$ , let it be 80000000H.	
result	Reflects the results in a flag.	
Byte	Byte (8 bits)	
Halfword	Half word (16 bits)	
Word	Word (32 bits)	
+	Addition	
_	Subtraction	
П	Bit concatenation	
×	Multiplication	
÷	Division	
%	Remainder from division results	
AND	Logical product	
OR	Logical sum	
XOR	Exclusive OR	
NOT	Logical negation	
logically shift left by	Logical shift left	
logically shift right by	Logical shift right	
arithmetically shift right by	Arithmetic shift right	

## (4) Register symbols used in execution clock

Register Symbol	Explanation	
i	f executing another instruction immediately after executing the first instruction (issue).	
r	If repeating execution of the same instruction immediately after executing the first instruction (repeat).	
Ι	If using the results of instruction execution in the instruction immediately after the execution (latency).	

### (5) Register symbols used in flag operations

Identifier	Explanation	
(Blank)	lo change	
0	Clear to 0	
х	Set or cleared in accordance with the results.	
R	Previously saved values are restored.	

## (6) Condition codes

Condition Name (cond)	Condition Code (cccc)	Condition Formula	Explanation
V	0000	OV = 1	Overflow
NV	1000	OV = 0	No overflow
C/L	0001	CY = 1	Carry Lower (Less than)
NC/NL	1001	CY = 0	No carry Not lower (Greater than or equal)
Z/E	0010	Z = 1	Zero Equal
NZ/NE	1010	Z = 0	Not zero Not equal
NH	0011	(CY or Z) = 1	Not higher (Less than or equal)
Н	1011	(CY or Z) = 0	Higher (Greater than)
Ν	0100	S = 1	Negative
Р	1 1 0 0	S = 0	Positive
т	0101	-	Always (Unconditional)
SA	1 1 0 1	SAT = 1	Saturated
LT	0110	(S xor OV) = 1	Less than signed
GE	1 1 1 0	(S xor OV) = 0	Greater than or equal signed
LE	0111	((S xor OV) or Z) = 1	Less than or equal signed
GT	1111	((S xor OV) or Z) = 0	Greater than signed

Notes 1. dddddddd: Higher 8 bits of disp9.

- 2. 4 if there is an instruction that rewrites the contents of the PSW immediately before.
- 3. If there is no wait state (3 + the number of read access wait states).
- 4. n is the total number of list12 load registers. (According to the number of wait states. Also, if there are no wait states, n is the total number of list12 registers. If n = 0, same operation as when n = 1)
- 5. RRRRR: other than 00000.
- 6. The lower halfword data only are valid.
- 7. ddddddddddddddddd: The higher 21 bits of disp22.
- 8. ddddddddddddd: The higher 15 bits of disp16.
- 9. According to the number of wait states (1 if there are no wait states).
- **10.** b: bit 0 of disp16.
- 11. According to the number of wait states (2 if there are no wait states).

- **Notes 12.** In this instruction, for convenience of mnemonic description, the source register is made reg2, but the reg1 field is used in the opcode. Therefore, the meaning of register specification in the mnemonic description and in the opcode differs from other instructions.
  - rrrrr = regID specification
  - RRRRR = reg2 specification
  - 13. iiiii: Lower 5 bits of imm9.
    - IIII: Higher 4 bits of imm9.
  - **14.** In the case of reg2 = reg3 (the lower 32 bits of the results are not written in the register) or reg3 = r0 (the higher 32 bits of the results are not written in the register), shortened by 1 clock.
  - 15. sp/imm: specified by bits 19 and 20 of the sub-opcode.
  - **16.** ff = 00: Load sp in ep.
    - 01: Load sign expanded 16-bit immediate data (bits 47 to 32) in ep.
    - 10: Load 16-bit logically left shifted 16-bit immediate data (bits 47 to 32) in ep.
    - 11: Load 32-bit immediate data (bits 63 to 32) in ep.
  - **17.** If imm = imm32, n + 3 clocks.
  - **18.** rrrrr: Other than 00000.
  - 19. ddddddd: Higher 7 bits of disp8.
  - 20. dddd: Higher 4 bits of disp5.
  - 21. dddddd: Higher 6 bits of disp8.
  - **22.** Do not make a combination that satisfies all the following conditions when using the "MUL reg1, reg2, reg3" instruction and "MULU reg1, reg2, reg3" instruction. Operation is not guaranteed when an instruction that satisfies the following conditions is executed.
    - Reg1 = reg3
    - Reg1 ≠ reg2
    - Reg1 ≠ r0
    - Reg3 ≠ r0

	Modification of timing in Figure 6-23 Timing of DMA Flyby Transfer (SDRAM $\rightarrow$ External I/O)	
	Modification of timing in Figure 6-24 Timing of DMA Flyby Transfer (External I/O $\rightarrow$ SDRAM)	
	Modification of description and addition to Caution in Table 6-5 Relationship Between Transfer Type and Transfer Object	
	Addition of description in 6.8 Next Address Setting Function	
	Addition of Cautions in 6.9 DMA Transfer Start Factors	
	Modification of description in 6.13 Times Related to DMA Transfer	
	Modification of description in 6.15 (3) Bus arbitration for CPU	
	Addition of 6.15 (7) Read values of DSAn and DDAn registers	
	Modification of Note in Figure 7-14 Pipeline Operation at Interrupt Request Acknowledgment (Outline)	CHAPTER 7 INTERRUPT/EXCEPTIO PROCESSING FUNCTIO

Edition	Major Revision from Previous Edition	Applied to:
2nd	Modification of selection of SSCG output by PLLSEL pin and MDL-Selector Table (modulation period) in <b>8.1 Features</b>	CHAPTER 8 CLOCK GENERATION FUNCTION
	Addition to <b>Cautions</b> and modification of description in <b>8.3.1 Clock control register</b> (CKC)	
	Modification of sample coding <2> for data setting sequence of clock source select register (CKS) in <b>8.3.2 Clock source select register (CKS)</b>	
	Modification of description in 8.3.3 SSCG control register (SSCGC)	
	Addition of Caution in 8.3.4 USB clock control register (UCKC)	
	Modification of oscillation stabilization time in 8.3.6 Oscillation stabilization time select register (OSTS)	
	Addition to Notes in Table 8-1 Operation Status of Each Clock	
	Modification of description in Table 8-2 Frequency List	
	Addition of 8.5 Operating Clock Provisions	
	Modification of oscillation stabilization time in Table 8-11 Counting Time Examples	
	Addition to Caution in 9.1.5 (2) Timer mode control registers C01 to C51 (TMCC01 to TMCC51)	CHAPTER 9 TIMER/ COUNTER FUNCTION
	Modification of Figure 9-7 TMC1 Compare Operation Example (Set/Reset Output Mode)	(REAL-TIME PULSE UNIT)
	Addition of noise elimination width when fx = 150 MHz in <b>Table 9-6 Relationship</b> Between NCW1n Register Set Value and Noise Elimination Width	
	Addition of 9.3.7 (6) Overflow interrupt signal (INTOV1n) and underflow interrupt signal (INTUD1n)	
	Modification of transfer rate in 10.2.1 Features	CHAPTER 10 SERIAL

	Addition of description in 10.2.3 (4) UARTBn transmit data register (UBnTX) (n = 0, 1)	
	Modification of description in <b>10.2.3 (5) UARTBn receive data register AP</b> (UBnRXAP), UARTBn receive data register (UBnRX) (n = 0, 1)	
	Addition and modification of description in 10.2.3 (6) UARTBn FIFO control register 0 (UBnFIC0) (n = 0, 1)	
	Modification of description in 10.2.3 (7) UARTBn FIFO control register 1 (UBnFIC1) (n = 0, 1)	
	Addition of description in 10.2.4 (5) (b) FIFO mode	
	Addition of description in 10.2.5 (2) Pending mode/pointer mode	
	Addition of Note in 10.2.5 (2) (a) (i) During transmission (writing to transmit FIFOn)	
	Addition of Note in 10.2.5 (2) (a) (ii) During reception (reading from receive FIFOn)	
	Addition of description in 10.2.6 (4) (c) (ii) Reception timeout interrupt (UBTITOn) (in FIFO mode only)	CHAPTER 10 SERIAL INTERFACE FUNCTION
	Addition of value when fx = 150 MHz in <b>Table 10-4 Baud Rate Generator Setting Data</b>	

Edition	Major Revision from Previous Edition	Applied to:
2nd	Addition of 10.2.8 Control flow	CHAPTER 10 SERIAL
	Modification of description in Figure 10-22 Block Diagram of Clocked Serial Interfaces 30 and 31	INTERFACE FUNCTION
	Modification of description of Caution 2 in 10.3.3 (1) Clocked serial interface mode registers 30, 31 (CSIM30, CSIM31)	
	Modification of description in 10.3.3 (2) Clocked serial interface clock select registers 30, 31 (CSIC30, CSIC31)	
	Addition of description in 10.3.3 (3) Receive data buffer registers 30, 31 (SIRB30, SIRB31)	
	Addition of description in 10.3.3 (4) Transmit data CSI buffer registers 30, 31 (SFDB30, SFDB31)	
	Modification of description in 10.3.3 (5) CSIBUF status registers 30, 31 (SFA30, SFA31)	
	Modification of example in Caution 2 in 10.3.4 (2) Baud rate	
	Modification of description in Figure 10-25 Transfer Data Length: 8 Bits (CCLn3 to CCLn0 Bits = 1000 in CSIL3n Register), Transfer Direction: MSB First (DIRn Bit = 0 in CSIM3n Register)	
	Modification of description in Figure 10-26 Transfer Data Length: 8 Bits (CCLn3 to CCLn0 Bits = 1000 in CSIL3n Register), Transfer Direction: LSB First (DIRn Bit = 1 in CSIM3n Register)	
	Deletion of description of 10.3.5 (7) Slave mode	
	Modification of Figure 10-30 Slave Mode (CKPn and DAPn Bits = 00 in CSIC3n Register, CCLn3 to CCLn0 Bits = 1000 in CSIL3n Register (Transfer Data Length: 8 Bits))	
	Modification of description in Figure 10-32 Continuous Mode	
	Modification of description in 10.3.5 (11) Transmission mode	
	Addition of description in 10.3.5 (12) Reception mode	
	Deletion of description in 10.3.5 (16) (a) SCKn pin	
	Modification of description in Table 10-8 Default Output Level of SCKn Pin	
	Modification of description of (1) to (12) in 10.3.6 Usage	
	Addition of Caution in 11.1 Overview	CHAPTER 11 USB
	Addition of items in Table 11-2 Correspondence Between Requests and Decoded Values	FUNCTION CONTROLLER (USBF)
	Addition of description in 11.4.1 (3) UF0 EPNAK register (UF0EN)	
	Deletion of description in 11.4.1 (9) UF0 EP status 1 register (UF0EPS1)	
	Modification of description in 11.4.1 (11) UF0 INT status 0 register (UF0IS0)	
	Modification of description in 11.4.1 (34) UF0 mode status register (UF0MODS)	
	Modification of description in 11.4.3 (2) UF0 EP0 status register L (UF0E0SL)	
	Modification of description in 11.4.3 (9) UF0 address register (UF0ADRS)	
	Modification of description in 11.4.3 (10) UF0 configuration register (UF0CNF)	
	Modification of description in 11.4.3 (11) UF0 interface 0 register (UF0IF0)	
	Modification of description in <b>11.4.3 (12) UF0 interface 1 to 4 registers (UF0IF1 to UF0IF4)</b>	

Edition	Major Revision from Previous Edition	Applied to:
2nd	Modification of <b>Caution 2</b> in <b>11.4.3 (14) UF0 device descriptor registers 0 to 17</b> (UF0DD0 to UF0DD17)	CHAPTER 11 USB FUNCTION
	Modification of Caution 2 in 11.4.3 (15) UF0 configuration/interface/endpoint descriptor registers 0 to 255 (UF0CIE0 to UF0CIE255)	CONTROLLER (USBF)
	Modification of Caution in 11.4.4 (1) USB function 0 DMA channel select register (UF0CS)	
	Deletion of Caution in Table 11-8 FW-Supported Standard Requests	
	Modification of description in Figure 11-15 Automatically Processed Requests for Control Transfer	
	Modification of description in Figure 11-20 CPUDEC Request for Control Transfer	
	Modification of description in Figure 11-30 USB Connection Example	
	Addition of value when fx = 150 MHz in Table 12-1 Setting of A/D Conversion Operation Time	CHAPTER 12 A/D CONVERTER
	Addition of 12.9 How to Read A/D Converter Characteristics Table	
	Modification of repeat frequency in 13.1 Features	CHAPTER 13 PWM UNIT
	Modification of description in Figure 13-1 Block Diagram of PWM Unit	
	Modification of description in 13.3 (1) PWM control registers 0 and 1 (PWMC0 and PWMC1)	
	Modification of description in 13.4.2 (1) Setting for starting PWM operation	
	Modification of description in Table 13-1 Repeat Cycle of PWMn	
	Modification of Caution in 14.3.8 Port DH	CHAPTER 14 PORT
	Modification of <b>Caution</b> and description on bit 0 in <b>14.3.8 (2) (c) Port DH function</b> control register (PFCDH)	FUNCTIONS
	Addition to Caution in 14.3.10 (2) (c) Port CT function control register (PFCCT)	
	Addition of noise elimination width when fx = 150 MHz in <b>Table 14-4 Relationship</b> Between NCW1n Register Set Value and Noise Elimination Width	
	Modification of value of program counter (PC) after reset in Table 15-2 Initial Value of CPU, Internal Data RAM, Internal Instruction RAM, and On-Chip Peripheral I/O After Reset	CHAPTER 15 RESET FUNCTIONS
	Modification of description in 16.1.1 (7) Mask function	CHAPTER 16 DEBUG FUNCTION (DCU)
	Addition of CHAPTER 17 ELECTRICAL SPECIFICATIONS (TARGET VALUES)	CHAPTER 17 ELECTRICAL SPECIFICATIONS
	Addition of CHAPTER 18 PACKAGE DRAWING	CHAPTER 18 PACKAGE DRAWING
	Addition of CHAPTER 19 RECOMMENDED SOLDERING CONDITIONS	CHAPTER 19 RECOMMENDED SOLDERING CONDITIONS
	Addition to Note in B.2 Instruction Set (in Alphabetical Order)	APPENDIX B INSTRUCTION SET LIST
	Addition of APPENDIX C REVISION HISTORY	APPENDIX C REVISION HISTORY
